#### Abstract

The origin of the broadening of NMR signals in 3-amino-4,5-dihydropyrazoles has been studied in the 1phenyl series. It has been proved that the broadening is due to the presence of acid in some solvents, like deuteriochloroform, by reproducing it by addition of trifluoroacetic acid. To determine the protonation site of 3-amino-1-phenyl-4,5-dihydropyrazole 1, the crystal structure of its picrate 5 was determined. Contrary to other dihydropyrazoles, $\mathbf{1}$ protonates on $\mathrm{N}^{2}$, like an amidine.

We reported several years ago, ${ }^{1-3}$ that 3 -amino-4,5-dihydropyrazoles, for instance 3-amino-1-phenyl-4,5-dihydropyrazole 1 , presented an intriguing and unexplained behaviour in ${ }^{1} \mathrm{H}$ NMR spectroscopy: under some conditions, the spectra in deuteriochloroform were so broad that no signal other than that of the $\mathrm{Me}_{4} \mathrm{Si}$ could be observed. This fact was also observed in the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of biologically active 3-amino-1-aryl-4,5-dihydropyrazoles [e.g., in 3-amino-1-( $m$ -trifluoromethylphenyl)-4,5-dihydropyrazole the anti-inflammatory agent BW-755C, 2]. ${ }^{4}$

This broadening of signals could be attributed either to slow prototropic exchange rates between tautomeric species and/or to slow equilibria between neutral and protonated forms.

Thus, we decided first to reproduce on modern spectrometers and under different experimental conditions, the broadening observed in the past using $60 \mathrm{MHz},{ }^{1.2}$ or 100 MHz instruments, ${ }^{4}$ in order to provide a possible explanation.

## Experimental

The title compounds 1, 3-amino-4-methyl-1-phenyl-4,5-dirydropyrazole 3, 3-ethylamino-1-phenyl-4,5-dihydropyrazole 4 and 3-amino-1-methyl-1-phenyl-4,5-dihydropyrazol-1-ium iodide 8 were prepared according to previously described methods. ${ }^{1.2}$ The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra in solution were recorded on a Bruker AC200 instrument working at 200.13 $\left({ }^{1} \mathrm{H}\right)$ and $50.32 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$ using standard conditions. ${ }^{5}$ The ${ }^{13} \mathrm{C}$ CPMAS spectrum was recorded in the same instrument using the conditions described in ref. 6.

## X.-Ray structure determination

Crystals of 3-amino-1-phenyl-4,5-dihydropyrazol-2-ium picrate 5 suitable for X-ray analysis were obtained by slow evaporation of a saturated ethanol solution.

Crystal data. $\mathrm{C}_{9} \mathrm{H}_{11} \mathrm{~N}_{3} \cdot \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{~N}_{3} \mathrm{O}_{7}, \quad M=390.3$, a well formed yellow prism of $0.18 \times 0.22 \times 0.56 \mathrm{~mm}$ was used for data collection at room temperature. Monoclinic $a=7.717(3)$,

[^0]

5
$b=11.147(3), c=20.076(2) \AA, \beta=98.60(2), V=1707.5 \AA^{3}$, space group $P 2_{1} / c, Z=4, D_{\mathrm{x}}=1.518 \mathrm{~g} \mathrm{~cm}^{-3}, \mathrm{Cu}-\mathrm{K} \alpha(\mathrm{Ni}$ filtered).

Data collection and processing. Siemens AED diffractometer using $\theta / 2 \theta$ scan mode, scan speed $3 / 12 \mathrm{deg} \mathrm{min}^{-1}$, scan width $(1.20+0.14 \tan \theta)$ and $\theta$ in the range $3<\theta<70$ deg. Cell parameters were determined by least-squares fit to observed $2 \theta$ values for 29 centred reflections with $22.3<$ $\theta<40.6$. Intensity checks for one standard reflection showed no significant variation. 3251 independent reflections were measured ( $h-2$ to $9, k-13$ to $10, l-24$ to 24 ) of which 1859 were observed with $l>2 \sigma(I)$. Lorentz and polarization (LP) and extinction corrections but no absorption was applied.

Structure analysis and refinement. The structure was solved by direct methods using SIR $92^{7}$ and refined using SHELX-92 ${ }^{8}$ by full-matrix least squares on $F_{0}$ with anisotropic thermal parameters (rigid-body constraint for the two phenyl rings). Many H atoms (e.g. H1N2, H1N and H2N) were identified in the difference map, but all of them were constructed with the geometric options allowed in SHELX-92 and refined with isotropic $U$ values. The weighting scheme $w=1 /\left[s\left(F_{0}{ }^{2}\right)+\right.$ $\left.(0.06 P)^{2}+0.0122 P\right]$ where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$, gave satisfactory agreement analyses. Max thermal value $10.02 \AA^{2}$, final $\Delta F$ peaks $0.70 \mathrm{e} \AA^{-3}$. The final $R$ indexes were respectively $R=$ 0.0620 for 1859 reflections with $F_{0}>4 \sigma\left(F_{0}\right)$ and 0.0996 for all the 3251 data. ${ }^{\|}$

All the calculations were performed on the Gould computer system of the Centro di Strutturistica Diffrattometrica del CNR,

[^1]Parma, Italy. The SIR 92 program was the PC version. Geometric and ancillary calculations were performed with PARST ${ }^{9}$ and CRYSRULER ${ }^{10}$ packages; drawings were made with ORTEX, ${ }^{11}$ the McArdle version of the ORTEP.

## Results and discussion

${ }^{1}$ H NMR spectroscopy
If we consider, for instance, the case of 3 -amino-1-phenyl4,5 -dihydropyrazole 1 , this compound could exist in three tautomeric forms: 3 -amino-4,5-dihydropyrazole 1a, 3 -amino-2,5-dihydropyrazole 1b and 3-imino-2,3,4,5-tetrahydropyrazole 1 c .

However, compound 6 was prepared ${ }^{2}$ and it continues to show broad signals, ${ }^{2}$ this observation excludes 1a/1c and $\mathbf{1 b} / \mathbf{1 c}$ tautomerism as being the origin of the observed broadening in spectra of 1 . A compound closely related to 7 was also prepared, ${ }^{1}$ and showed a similar broadening, but in this case a tautomeric process involving an iminotetrahydropyrazole (an $\mathrm{N}^{2}$-methyl derivative of 1c) cannot be excluded. Thus, a slow tautomeric process involving 1a and $\mathbf{1 b}$ remains as a possible explanation for the broadening of ${ }^{1} \mathrm{H}$ NMR spectra of 1 .

Nevertheless, when spectra are recorded in the presence of various amounts of trifluoroacetic acid, drastic modifications are observed. In Figs. 1-3 are represented the ${ }^{1} \mathrm{H}$ NMR spectra of dihydropyrazoles 1,5 and 6 in $\mathrm{CDCl}_{3}$ solution. Figures a correspond to the spectra recorded using $\mathrm{CDCl}_{3}$ from a freshly open bottle and figures $\mathbf{b}$ to spectra of the same solutions after addition of small amounts of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$. Using $\mathrm{CDCl}_{3}$ exposed to light, spectra similar (more or less broadened) to figures $\mathbf{b}$ are obtained. In the case of the 4,5-dihydropyrazole 1, the spectra correspond to the following chemical shifts: neutral form (Fig. 1a) $\delta 2.88(4 \mathrm{a}-\mathrm{H}, 4 \mathrm{~b}-\mathrm{H}), 3.68(5 \mathrm{a}-\mathrm{H}, 5 \mathrm{~b}-\mathrm{H})$ ( $\mathrm{AA}^{\prime} \mathrm{BB}^{\prime}$ system of the pyrazole ring), $6.95\left(2^{\prime}-\mathrm{H}, 6^{\prime}-\mathrm{H}\right), 7.24\left(3^{\prime}-\mathrm{H}, 5^{\prime}-\mathrm{H}\right), 6.76$ ( $\left.4^{\prime}-\mathrm{H}\right)\left(\mathrm{AA}^{\prime} \mathrm{BB}^{\prime} \mathrm{C}\right.$ system of the N -phenyl substituent); protonated form ( 2 mg of pyrazole in $0.5 \mathrm{~cm}^{3}$ of $\mathrm{CDCl}_{3}$ plus $2 \mathrm{~mm}^{3}$ of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$, Fig. 1c) $\delta 3.13(4 \mathrm{a}-\mathrm{H}, 4 \mathrm{~b}-\mathrm{H}), 3.90(5 \mathrm{a}-\mathrm{H}$, $5 \mathrm{~b}-\mathrm{H})\left(\mathrm{AA}^{\prime} \mathrm{BB}^{\prime}\right.$ system of the pyrazole ring), $6.99\left(2^{\prime}-\mathrm{H}, 6^{\prime}-\mathrm{H}\right)$, $7.36\left(3^{\prime}-\mathrm{H}, 5^{\prime}-\mathrm{H}\right), 7.13\left(4^{\prime}-\mathrm{H}\right)$ ( $\mathrm{AA}^{\prime} \mathrm{BB}^{\prime} \mathrm{C}$ system of the $N$-phenyl substituent).
These results pointed to the presence of DCl , formed by photolysis of $\mathrm{CDCl}_{3}$, as the origin of the broadening described in earlier references. ${ }^{1-4}$ To verify this hypothesis, two kinds of experiments were carried out: ( $i$ ) addition of 'proton sponge' ( 1,8 -bisdimethylaminonaphthalene) slowly transformed ( 24 h ) spectra of figures $\mathbf{b}$ into those of figures $\mathbf{a}$; (ii) by addition of a great excess of $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$, the signals of the spectra became narrow again (Fig. 1c), but all of them are shifted downfield.

Other unpublished results, ${ }^{12.13}$ are also consistent with traces of acid being at the origin of the broad signals. For

Fig. $1{ }^{1} \mathrm{H}$ NMR spectra of the dihydropyrazole 1
instance, the broadening has never been observed in [ ${ }^{2} \mathrm{H}_{6}$ ]DMSO nor in $\left[{ }^{2} \mathrm{H}_{5}\right.$ ]pyridine.

Fig. $2{ }^{1} \mathrm{H}$ NMR spectra of the dihydropyrazole 3
Another interesting observation is that the broadening was rather insensitive to temperature changes. ${ }^{1-3}$ This point could te puzzling as for $\ln k$ to be independent of temperature (in the range explored, -70 to $+70^{\circ} \mathrm{C}$ ), $\Delta H^{t}$ has to be very small and $\Delta S^{\ddagger}$ very large and negative. Nevertheless, it must be considered that if the concentration of protons, $C_{\mathrm{H}^{+}}$, is very low, then $\Delta S^{\ddagger}($ obs $)=R \ln C_{\mathrm{H}^{+}}+\Delta S^{\ddagger}$, should appear as very large and negative. ${ }^{14}$

Unfortunately, important broadening can be reproduced by simulation using the Binsch DNMR4 program ${ }^{15}$ only when the ratio $[\mathrm{B}] /\left[\mathrm{BH}^{+}\right]$is not too high (below 5). Obviously, this simulation uses an oversimplified model, assuming that two $\mathrm{A}^{\prime} \mathrm{A}^{\prime} \mathrm{BB}^{\prime}$ (or two $\mathrm{AA}^{\prime} \mathrm{BB}^{\prime} \mathrm{C}$ for the phenyl group) are exchanging with each other (one of the neutral molecule and one of the protonated form). For example, the equilibrium 1a/1b cannot be simulated since an $\mathrm{AA}^{\prime} \mathrm{BB}^{\prime}$ is exchanging with an $\mathrm{A}_{2} \mathrm{XY}$ system in which one proton (the proton on $\mathrm{N}^{2}$ ) belongs partially to the solvent. Chemical shifts were those corresponding to the spectrum of Fig. 1a for the neutral species and of Fig.

Fig. $3{ }^{1} \mathrm{H}$ NMR spectra of the dihydropyrazole 4

1c for the protonated molecule. We used approximate coupling constants ${ }^{16}$ and a T2 of 0.6 s for both entities. The result of the simulation is represented in Fig. 4.

Having established that the broadening of the signals is due to the presence of the conjugated acid, the structure of the protonated form is still to be determined.
All the spectroscopic evidence indicates that the major tautomer has the structure 1a. In the solid state, the X-ray structures of compounds $\mathbf{1}$ and $\mathbf{2}$ have been determined: ${ }^{17}$ they both exist as 3 -amino-4,5-dihydropyrazoles $1 \mathbf{a}$ and $\mathbf{2 a}$.
This observation is related to the protonation site of 3-amino-4,5-dihydropyrazoles. Taking for granted that these compounds, for instance 1, exist as tautomer 1a (the X-ray structure of 4,5-dihydropyrazole hydrochloride is known ${ }^{18}$ and corresponds to a structure like $\mathbf{1 0}$ but with two protons on $\mathrm{N}^{1}$, see 14) there are three possible conjugated acids: 1d, protonated on $\mathrm{N}^{1}$, $\mathbf{1 e}$, protonated on $\mathrm{N}^{2}$, and $\mathbf{1 f}$, protonated on the exocyclic amino group.

4,5-Dihydropyrazoles, for instance 3-methyl-1-phenyl-4,5dihydropyrazole 9 , protonate and quaternarize at position 1 to afford cations 10 and $11 .{ }^{19.20}$ It is also known that dihydropyrazole 1 quaternarizes at position 1 affording salt

Fig. $4{ }^{1} \mathrm{H}$ NMR simulated spectra of the dihydropyrazole $\mathbf{1}$ : $[\mathrm{B}] /[\mathrm{BH}]=99: 1(a) ; 95: 5(b) ; 90: 10(c) ; 80: 20(d)$
8. ${ }^{21-23}$ It was tempting to assume that protonation of 1 also occurs at position 1 with formation of cation 1d. Nevertheless, if protonation on the amino group seems highly improbable, protonation on $\mathrm{N}^{2}$ leading to a cation 1 e stabilized by resonance, like the amidinium cation, is reasonable (amidrazones, which have the same functionality as 3 -aminodihydropyrazoles, protonate on $\mathrm{N}^{2}$ ). ${ }^{24}$

9

10

11

12

Although protonation of 'normal' dihydropyrazoles, that is, dihydropyrazoles without amino groups at position 3, takes place exclusively at position 1 , it is possible to obtain both quaternary salts, 11 by direct quaternization and 12 by protonation of the corresponding 2,5-dihydropyrazole. ${ }^{25}$ The study of model compounds $\mathbf{1 1}$ and $\mathbf{1 2}$ leads to some rules concerning the effect of a positive charge on NMR properties: (i) in ${ }^{1} \mathrm{H}$ NMR, if the charge is at position 1, there is a decrease in the sum of vicinal coupling constants of the $\mathrm{CH}_{2} \mathrm{CH}_{2}$ fragment $\left(\Sigma J=J_{\text {cis }}+J_{\text {trans }}\right)$, this decrease amounts to 6.5 Hz , on the other hand, if the charge is at position 2 , there is almost no effect on $\Sigma J{ }^{26}$ (ii) in ${ }^{13} \mathrm{C}$ NMR, the most striking observation concerns the signal of the carbon atom at the para position of the $N$-phenyl ring: in $\mathbf{9}$ it appears at 118 ppm , in $\mathbf{1 0}$

Fig. 5 Perspective view of compound 5 with the atomic numbering scheme used

Fig. 6 Hydrogen bond network (simplified) of compound 5
at 132.5 ppm , in 11 at 132 ppm (the ${ }^{13} \mathrm{C}$ NMR spectrum of 12 has not been reported). ${ }^{27-29}$

For 3-amino-1-phenyl-4,5-dihydropyrazole, the spectrum recorded in $\mathrm{CDCl}_{3}$ corresponds to $\Sigma J=18.6 \mathrm{~Hz}, \delta\left(\mathrm{C}^{\prime}\right)=$ 117.9 while the spectrum recorded in a $\mathrm{CDCl}_{3}-\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ mixture (narrow signals) corresponds to $\Sigma J=16.3 \mathrm{~Hz}$, $\delta\left(\mathrm{C}^{\prime}\right)=125.8$ (pure $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$, Table 3). For compound 8 in $\left[{ }^{2} \mathrm{H}_{6}\right.$ ]DMSO, the $\mathrm{CH}_{2} \mathrm{CH}_{2}$ system appears as an ABCD system (spectroscopic proof that quaternization took place at position 1 ) and $\delta\left(\mathrm{C}^{\prime}\right)=130.0$ (Table 3).

The conclusion is that protonation of compound 1 does not occur at position 1, at least not at the extent that it occurs in the case of compound 9 . To clarify this matter it was decided to prepare the picrate of 1 , salt 5 , and to determine its structure by X-ray crystallography. Also, the ${ }^{13}$ C CPMAS NMR spectra of 1 and 5 , were recorded. The results of Table 1 show that the chemical shifts of compound 1 in solution and in the solid state were almost identical, and since the solid state structure of 1 corresponds to tautomer 1a so it will be for the solution. The ${ }^{13} \mathrm{C}$ chemical shifts of the picrate 5 in the solid state (this compound is very insoluble in $\left[{ }^{2} \mathrm{H}_{6}\right] \mathrm{DMSO}$ ) and those of 1 and 5 in $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ are also similar, although differences of 3-4 ppm are observed.

## X-Ray structure of compound 5

A.n ORTEP view of compound 5 with the atomic numbering scheme used is shown in Fig. 5 and a PLUTO drawing with a simplified hydrogen bond network is represented in Fig. 6. The N1-C5 single bond distance is in agreement with those of the compounds reported in the Cambridge Structural Database (CSD) ${ }^{30}$ and in Table 2 in which a comparison with the dhydropyrazole part of three compounds is performed (1 GERBOU, ${ }^{17} 13$ DPPRZL ${ }^{21}$ and 14 PYZOLC ${ }^{18}$ are the reference codes of the compounds as classified by the CSD). The N2-C3 distance corresponds well with the mean value of those generally assumed for the $\mathrm{N}-\mathrm{C}$ double bond ${ }^{30}$ and is intermediate between those of $\mathbf{1}$ and 13. On the other hand, the $\mathrm{N} 1-\mathrm{N} 2$ bond length is consistent with the $\mathrm{N}-\mathrm{N}$ single bond and compares well with that of 1 ; the same is verified also for the $\mathrm{C} 3-\mathrm{C} 4$ and C4-C5 distances of the 4,5 -dihydropyrazole ring.

13

14

It must be observed that the C3-N18 distance of the title compound 5 is the shortest one, even shorter than that reported in ref. 30 for a $\mathrm{C}-\mathrm{N}$ double bond; probably, the conjugation

| Llamas-Saiz ${ }^{39}$ | 1.269 | 1.456 | 1.215 |
| Frydenvang ${ }^{40}$ | 1.242 | 1.456 | 1.232 |

${ }^{a}$ Mean value in molecule.
with the phenyl ring is also responsible for the shortening of the C6-N1 distance.

Simple resonance considerations, represented above, account for these observations: (i) protonation on N 1 suppress the 'enamine-like' resonance of 4,5 -dihydropyrazoles, ${ }^{31}$ this produces an increase ( $+0.13 \AA$ ) of the N1-N2 bond and a decrease of the $\mathrm{N} 2-\mathrm{C} 3$ bond ( $-0.08 \AA$ ); (ii) a 3 -amino group introduces an amidine-like resonance which opposes the preceding one, this results in an increase $(+0.10 \AA)$ of the $\mathrm{N} 1-\mathrm{N} 2$ bond and a small decrease of the $\mathrm{N} 2-\mathrm{C} 3$ bond ( $-0.06 \AA$ ); (iii) protonation on N2 does not affect the N1-N2 bond length but, due to the amidinium cation resonance, increases the $\mathrm{N} 2-\mathrm{C} 3$ bond length $(+0.04 \AA)$ and decreases the exocyclic C3-N18 bond length ( $-0.05 \AA$ ).

Concerning bond angles, it can be said that the C3-C4-C5 and $\mathrm{N} 1-\mathrm{C} 5-\mathrm{C} 4$ angles are similar in all compounds, the $\mathrm{N} 2-$ N1-C6 and N2-N1-C5 are shorter in 5 than in 1, the remaining ones significantly greater, no trend being discernible on the examined compounds. The orientation of the phenyl ring with respect to the pyrazole one, defined by the torsion angle $\mathrm{N} 2-$ N1-C6-C7, is quite different in 1 (15.0) and in 5 (60.8). This increase is probably related to the replacement of the lone pair of N2 by a hydrogen atom linked to a bulky picrate anion (in 1 -phenylpyrazole, the dihedral angle increases from $26^{\circ}$ in the neutral molecule ${ }^{32}$ to $38^{\circ}$ in the cation). ${ }^{3}$

The puckering parameters (puckering amplitude $q_{2}$ and phase angle $\varphi_{2}$ ) corresponding to molecules $1,5,13$ and 14 are also reported in Table $2 .{ }^{34}$ It can be noted that compound 14 (4,5-dihydropyrazol-1-ium cation) is planar and the 1,3diphenyl derivative is nearly planar with a twist conformation. The dihydropyrazole 1 and its picrate 5 both have envelope conformations.

As far as the picrate part of the compound is concerned, it can be said that everything is in agreement with other picrates, as can be seen from Table 3 in which the mean distances of the oxidryl and nitro groups of 5 are compared with the results reported in the work of Walkinshaw ${ }^{37}$ cited by Botoshansky et al. ${ }^{38}$ and with the picrate of a pyrazole derivative. ${ }^{39}$ The C10O19 distance is longer in compound 5 probably because the O19 atom is involved in hydrogen bonds.

A number of hydrogen bonds makes the crystal significantly well packed (density $=1.518 \mathrm{~g} \mathrm{~cm}^{-3}$, packing coefficient $=$ 0.695 ).

## Conclusions

It remains to be explained why broadening of signals due to the presence of acids is only observed for 3 -amino- 4,5 -dihydropyrazoles and not at all for 'normal' dihydropyrazoles. We think that the reason might be the high thermodynamic and kinetic basicities of the former compounds. 'Normal' dihydropyrazoles have $\mathrm{p} K_{\mathrm{a}}$ values in the range $4-6,{ }^{41}$ those of 3 -aminodihydropyrazoles are not known (amidrazones have a $\mathrm{p} K_{\mathrm{a}}=10.0$ ), ${ }^{24}$ and since there are two conjugated acids in equilibrium, the thermodynamic values should be difficult to determine. The fact that the effect produced by adding protons can be reversed by 'proton Sponge' but that the reversibility is slow is a proof of the high kinetic basicity.
