#### Abstract

The structure of $(E)$-3,4-dibromotetrahydrothiophene 1,1-dioxide, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$, has been determined at 150 K by X-ray crystallography and in the gas phase by electron diffraction constrained using bond length and angle differences calculated ab initio. The results show that in both phases the ring adopts the half-twist conformation with $C_{2}$ symmetry. However, in the solid phase the bromine atoms occupy equatorial positions, whereas in the gas phase the optimum fit is for a mixture of axial and equatorial conformers. These are present in effectively equal amounts [proportion of axial conformer $47.2(23) \%$ ], as also predicted by ab initio calculations at the MP2/6-31G* level. Salient mean structural parameters ( $r / \mathrm{pm}$, angles/degrees) for the gas phase $\left(r_{\mathrm{a}}\right)$ and the solid phase, respectively, are: $r(\mathrm{~S}=\mathrm{O}) 142.5(1), 143.8(7) ; r(\mathrm{~S}-\mathrm{C}) 179.0(3), 179.7(18) ; r(\mathrm{C}-\mathrm{C})$ 152.9(4), 153.6(10); $r(\mathrm{C}-\mathrm{Br})$ 194.8(3), 194.7(10); OSO 117.9(10), 117.7(8); CSC92.8(7), 96.4(6); CCCC 55.9(10), $57.7(15) ; \mathrm{BrCCBr}$ (axial) $-167.9(18)$ and (equatorial) $-70.8(11)$, $-64.3(20)$. These values are in good agreement with those obtained in an ab initio (MP2/6-31G* level) study of the molecular geometry.

Contrary to expectation, addition of molecular bromine to 3-thiabicyclo[3.2.0]hept-6-ene 3,3-dioxide (1) yielded substantial

1
amounts of the cis-1,2-dibromide ( $1: 1$ mixture in dichloromethane of cis and trans isomers by NMR, confirmed by X-ray diffraction), ${ }^{1}$ suggesting that the remote $\mathrm{SO}_{2}$ group exerted an extraordinary directive influenced by means of a long-range coulomb interaction that stabilised an open carbocation intermediate at the expense of the usually favoured bridged bromonium ion. ${ }^{2}$ This unprecedented loss of stereoselection in the bromination of a non-conjugated alkene, caused by a remote $\mathrm{SO}_{2}$ group, prompted an investigation into the structural identity of the single isomers obtained in the corresponding bromination of 2,5-dihydrothiophene 1,1-dioxide (2). ${ }^{3}$ We have carried out a structural study of

2

3,4-dibromotetrahydrothiophene 1,1-dioxide, $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$ (3), in the solid phase by low-temperature single crystal X-ray diffraction and, for comparison, in the gas phase by electron diffraction. In the initial gas-phase structure determination of 3, the OSO and CSC bond angles were poorly determined. Therefore, ab initio calculations were obtained at a reasonable level of theory (MP2/6-31G*) as an aid in the gas phase structure determination of 3 .

3

## Experimental

X-Ray structure determination of $\mathrm{C}_{4} \mathbf{H}_{6} \mathrm{Br}_{2} \mathbf{S O}_{\mathbf{2}}$
A colourless plate ( $0.8 \times 0.4 \times 0.2 \mathrm{~mm}$ ) suitable for X-ray analysis was obtained by slow cooling of a saturated solution in ethyl acetate.

## Crystal data

$\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}, M=555.9$, orthorhombic, space group $\mathrm{Pbc} 2_{1}$, $a=543.2(2), b=1299.4(1), c=2129.8(16) \mathrm{pm}, U=1.5033$ $\mathrm{nm}^{3}$ (from accurate $2 \theta$ values for 17 reflections with $2 \theta=10-$ $\left.20^{\circ}, \lambda=71.073 \mathrm{pm}\right), Z=8, D_{\mathrm{c}}=2.456 \mathrm{Mg} \mathrm{m}^{-3}, T=150 \mathrm{~K}$, $\mu=10.988 \mathrm{~mm}^{-1}, F(000)=1056$.

## Data collection and processing

Stoë Stadi-4 diffractometer equipped with an Oxford Cryosystems low temperature device, ${ }^{4} \mathrm{Mo}-\mathrm{K} \alpha$ radiation, $\omega-2 \theta$ scans using on-line profile-fitting, ${ }^{5} 1648$ data collected ( $2 \theta_{\text {max }} 55^{\circ}, h$ $0-7, k 0-16, l 0-22)$, of which 1370 had $\left|F^{2}\right|>2 \sigma\left(F^{2}\right)$. Three standard reflections were collected every 60 min ; the maximum drift was $1 \%$.

## Electron diffraction (ED) measurements

Electron scattering intensities were recorded on Kodak Electron Image plates using the Edinburgh gas-diffraction apparatus operating at $c a .44 .5 \mathrm{kV}$ (electron wavelength $c a .5 .7$ $\mathrm{pm}) .{ }^{6}$ Nozzle-to-plate distances were $c a .200$ and 260 mm , yielding data in the $s$ range $20-224 \mathrm{~nm}^{-1}$; two usable plates were obtained at each distance. The sample and nozzle were held at ca. 453 and 469 K , respectively, during the exposure periods.

The scattering patterns of benzene were also recorded for the purpose of calibration; these were analysed in exactly the same way as those of the 3,4-dibromotetrahydrothiophene 1,1 -dioxide so as to minimize systematic errors in the wavelengths and camera distances. Nozzle-to-plate distances, weighting functions used to set up the off-diagonal weight matrix, correlation parameters, final scale factors and electron wavelengths for the measurements are collected together in Table 1.

The electron scattering patterns were converted into digital form using a computer-controlled Joyce-Loebl MDM6 microdensitometer with a scanning program described elsewhere. ${ }^{7}$ The programs used for data reduction ${ }^{7}$ and least-squares refinement ${ }^{8}$ have been described previously; the complex scattering factors of Ross et al. were employed. ${ }^{9}$

## Theoretical calculations

$A b$ initio computations were performed employing standard methods, ${ }^{10}$ the GAUSSIAN92 program ${ }^{11}$ and the following basis set: for S and Br , quasi-relativistic MEFIT ${ }^{12}$ pseudopotentials ( 6 and 7 valence electrons, respectively), ${ }^{13,14,15}$ together with a valence 2 s 2 pld basis set contracted from the 4 s 4 pld primitive sets ${ }^{15,16}$ (d-exponents 0.65 and 0.348 for $S$ and Br , respectively ${ }^{17}$ ); for $\mathrm{C}, \mathrm{O}$ and H a standard $6-31 \mathrm{G}^{*}$ basis set. ${ }^{10}$ Five Cartesian d-functions were used throughout. This basis set is of split-valence double zeta plus polarization quality and is, for simplicity, referred to as $6-31 \mathrm{G}^{*}$.

Geometries were fully optimized at the SCF level in the given symmetry. Harmonic frequencies were computed numerically, followed by re-optimization at the electron-correlated MP2 level. Unless otherwise noted, energies are given at the MP2/6-31G* level (employing the MP2/6-31G* optimized geometries) including SCF/6-31G* zero point corrections (scaled by 0.89 ). ${ }^{10}$

## Results

## X-Ray structure solution and refinement

At first a data set collected at room temperature was used and was solved in the space group Pbca using SHELX-86. ${ }^{18}$ However, extensive disorder was evident and for further work data collected at 150 K were used. The structure was solved by substitution of the coordinates of a bromine atom from the room temperature data. The bromine atoms were found in the first Fourier map and the remaining non-hydrogen atoms were found in subsequent Fourier maps; the structure was refined with SHELXL-93. ${ }^{19}$ The low temperature data set is $P b c 2_{1}$, and not $P b c a$, as it has a significant number of weak reflections with $h$ odd in the zone $h 0 l$, and an average $\left|E^{2}-1\right|$ of 0.83 for all the data. The coordinates of the two independent molecules (differentiated by prime and non-prime) possess pseudo-symmetry relating them to one another; this was broken by making shifts in the

[^0]coordinates of one pair of bromine atoms as indicated by their anisotropic displacement parameters. Disorder was still observed in $\mathrm{C}(3)$ and $\mathrm{C}(4)$ of both molecules and two alternative positions with isotropic thermal parameters were included in the final model for each disordered atom. The relative site occupancy factors for the two disordered regions when refined converged to values of $0.66(3)$ and $0.79(3)$ for the non-prime and prime molecules, respectively. The bonds to $C(3)$ and $C(4)$ in both molecules were restrained to be equal with an effective standard deviation of $0.03 \AA$ as their positions are poorly determined. Hydrogen atoms were included at calculated positions. At final convergence, $w R_{2}=0.128$ for all data, $R_{1}=0.044$ for the 1370 data with $\left|F^{2}\right|>2 \sigma\left(F^{2}\right), S=1.09$ for 159 parameters and the final $\Delta F$ synthesis showed no peak outside the range -952-972e $\mathrm{nm}^{-3}$. The major peaks and troughs in the final $\Delta F$ synthesis are all located near the bromine atoms. The weighting scheme $w^{-1}=$ $\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+0.0794 P+4.46 P$, where $P=$ maximum of $\left(F_{\mathrm{o}}{ }^{2}\right.$ or $\left.0)+2 F_{\mathrm{c}}^{2}\right] / 3$, gave satisfactory agreement analyses and in the final cycle $(\Delta / \sigma)_{\text {max }}=0.004$. Tables of bond lengths and angles, fractional coordinates and thermal parameters have been deposited at the Cambridge Crystallographic Data Centre. For details of the deposition scheme, see 'Instructions for Authors', J. Chem. Soc., Perkin Trans. 2, 1995, Issue 1. Selected bond lengths and angles are given in Table 2. Plots of the structure, including the atom numbering scheme, are shown in Fig. 1 and the molecular packing in the crystal is shown in Fig. 2.

## ED Structural analysis: molecular model

Two models were used to generate atomic coordinates of $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{Br}_{2} \mathrm{SO}_{2}$ : model A described a single conformer, as found in the solid phase and model $\mathbf{B}$ (which was suggested by ab initio calculations) described a mixture of two conformers with $C_{2}$ symmetry as optimized in the theoretical study. The parameters used in model B, subsequently found to provide the optimum fit, are given in Table 3. The atomic coordinates for both models were generated as follows. The heavy atoms were defined by the S-C distance $\left(p_{2}\right)$, the mean $\mathrm{C}-\mathrm{C}$ distance ( $p_{3}=\{2 r[\mathrm{C}(2)-$ $\mathrm{C}(3)]+r[\mathrm{C}(3)-\mathrm{C}(4)]\} / 3)$ and difference $\{r[\mathrm{C}(2)-\mathrm{C}(3)]-$ $r[\mathrm{C}(3)-\mathrm{C}(4)]\}$, the CSC angle $\left(p_{7}\right)$, the $\mathrm{S}=\mathrm{O}$ distance $\left(p_{1}\right)$, the OSO angle ( $p_{6}$ ), the $\mathrm{C}-\mathrm{Br}$ distance ( $p_{4}$ ), the CCBr angle ( $p_{8}$ ) and the torsion angle $\operatorname{CCCBr}\left(p_{13}\right)$. The hydrogen atoms were defined by a common C-H distance ( $p_{5}$ ), the SCH and CCH angles, $\left(p_{9}\right)$ and ( $p_{10}$ ), and the torsion angles CSCH and CCCH,

Fig. 1 Thermal ellipsoid plot of one of the crystallographically independent molecules of $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$ showing the atom numbering scheme adopted and the additional atoms used to model the disorder about $C(3)$ and $C(4)$

${ }^{a}$ For definition of parameters, see the text. Figures in parentheses are the estimated standard deviations. ${ }^{b}$ esd from $R$-factor plot at $95 \%$ confidence level; $\mathrm{f}=$ fixed; $\mathrm{rf}=$ refined then fixed. 17 Additional differences were fixed at values calculated by ab initio.
$\left(p_{15}\right)$ and $\left(p_{16}\right)$. Model A allowed for both a twist and a tilt in the ring; the twist angle was defined by the torsion $\mathrm{C}(2)-\mathrm{M}(1)-$ $\mathrm{M}(2)-\mathrm{C}(3)$, where $\mathrm{M}(1)$ is the mid-point of the $\mathrm{C}(2) \cdots \mathrm{C}(5)$ interatomic distance and $\mathbf{M}(2)$ is at the mid-point of the $\mathrm{C}(3)-$ $\mathrm{C}(4)$ bond. The tilt angle was defined as the angle $\mathrm{S}(1)-\mathrm{M}(1)-$ $\mathbf{M}(2)$. Model B incorporated a different twist angle for each of the two conformers defined by a mean twist angle $\left[p_{11}=\right.$ $\frac{1}{2}$ (axial twist) $+\frac{1}{2}$ (equatorial twist)] and a difference between these angles $\left[p_{12}=\right.$ (axial twist) - (equatorial twist)]. A number of other small differences between bond distances, angles, etc. in the two conformers were incorporated into model B and were fixed at the values calculated $a b$ initio throughout the structure refinement.

## Refinement of the structure

The radial-distribution curve for $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$ consists of five well defined peaks at $c a .150,180,270,360$ and 440 pm and a broad feature at $c a .510 \mathrm{pm}$ (Fig. 3). The peak at $c a .150 \mathrm{pm}$ corresponds to the scattering from the bonded $\mathrm{S}=\mathrm{O}$ and $\mathrm{C}-\mathrm{C}$ pairs with a shoulder at $c a .110 \mathrm{pm}$ corresponding to the $\mathrm{C}-\mathrm{H}$ bond distance and the peak at $c a .180 \mathrm{pm}$ is due to the $\mathrm{S}-\mathrm{C}$ and $\mathrm{C}-\mathrm{Br}$ bonded distances. The peak at $c a .270 \mathrm{pm}$ corresponds to two bond distances, the most significant contribution coming from the $\mathrm{C} \cdots \mathrm{Br}$ distances. The remaining features in the radial-distribution curve define the conformation of the molecule, the principal contributions arising from the $\mathrm{S} \cdots \mathrm{Br}$ and $\mathrm{Br} \cdots \mathrm{Br}$ distances. The peak at $c a .510 \mathrm{pm}$ is mainly due to the $\mathrm{O} \cdots \mathrm{Br}$ distances.

The molecular parameters from the solid phase structure were used as the starting values for the refinement with the single conformer model A. With the OSO and CSC angles fixed at the mean solid phase values, refinement of the remaining parameters defining the heavy atom coordinates converged with an $R_{\mathrm{G}}$ factor of 0.189 . Refinements including the OSO and CSC angles gave unrealistic values when compared with the solid state parameters $\left\{\right.$ too high $\left[127.0(15)^{\circ}\right]$ and too low [88.4(6) ${ }^{\circ}$ ] respectively\}, the $R_{\mathrm{G}}$ factor remaining relatively large for this refinement at 0.132 .
The molecular parameters obtained from the theoretical axial and equatorial geometries and amplitudes of vibration obtained from their scaled $a b$ initio force fields were used as the starting values for the refinement with model B. Initially, owing to the effects of correlation, it was necessary to define weighted mean and difference parameters for the $\mathrm{S}=\mathrm{O}$ and $\mathrm{C}-\mathrm{C}$ distances [weighted mean $=\left(2 p_{1}+3 p_{3}\right) / 5$, difference $\left.=p_{1}-p_{3}\right]$ and

Fig. 3 Observed and final weighted difference radial-distribution curves for $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$. Before Fourier inversion, the data were multiplied by $s \times \exp \left[\left(-0.00002 s^{2}\right) /\left(Z_{\mathrm{Br}}-f_{\mathrm{Br}}\right)\left(Z_{\mathrm{C}}-f_{\mathrm{C}}\right)\right]$.
for the $\mathrm{S}-\mathrm{C}$ and $\mathrm{C}-\mathrm{Br}$ distances [weighted mean $=\left(p_{2}+p_{4}\right) / 2$, difference $\left.=p_{2}-p_{4}\right]$, unacceptable values being obtained for the freely refining distances. The differences in the bond lengths were set at the values calculated $a b$ initio. It was also necessary to fix the OSO angle in the initial refinements, because the O ...O distances contributed little to the peak at $c a .270 \mathrm{pm}$.
Ten of the parameters defining the molecular geometry could be refined simultaneously in the final analysis. The C-H bond distance was refined and subsequently fixed at a value which gave a lower $R_{\mathrm{G}}$ factor than that obtained with the theoretical value. The remaining parameters (those defining the bond and torsion angles to the hydrogen atoms and the difference twist angle) were fixed at values identical to the theoretical values. In addition, it was also possible to refine seven amplitudes of vibration. The vibrational amplitudes for bonded distances were refined then fixed subsequently, the remaining amplitudes were set at the theoretical values. Ratios used to constrain the amplitudes refining in groups were set at the theoretical values. A series of refinements was carried out with the proportion of the axial conformer ( $p_{15}$ ) fixed at various values over the range $35-55 \%$. \{The CSC angle ( $p_{7}$ ), the CCCBr difference angle ( $p_{14}$ ) and the amplitudes $u[\mathrm{~S}(1) \cdots \mathrm{Br}(8)]$ and $u[\mathrm{O}(2) \cdots \mathrm{Br}(9)]$ were removed from these refinements as they had high esds and were therefore rather unstable.\} A third-order polynomial was fitted to a plot of $R_{\mathrm{G}}$ vs. $p_{15}$, the minimum occurring with the proportion of axial conformer being $47.2(23) \%$, the error of this value being given at the $95 \%$ confidence level. ${ }^{20}$ Subsequently, $p_{15}$ was fixed at this value. The refinement converged with $R_{\mathrm{G}}=0.072$. An estimate of the error in the twist angle difference ( $p_{13}$ ) was obtained by including it in one cycle of least squares with a very low partial shift, giving a value of $5.4(21)^{\circ}$. For this optimum refinement, the structural details and vibrational amplitudes are listed in Tables 3 and 4, respectively, and the most significant part of the least-squares correlation matrix is shown in Table 5. Fig. 4 shows the experimental and difference molecular scattering intensity curves.

## Discussion

The disorder present in the single-crystal X-ray structure is consistent with ( $E$ )-3,4-dibromotetrahydrothiophene 1,1 -dioxide with equatorial bromine atoms. A disordered cisdibromide isomer was discounted as the distances between the two components of the disorder within a given molecule are too

Fig. 4 Observed and final weighted difference molecular scattering intensity curves for $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{SO}_{2} \mathrm{Br}_{2}$. Nozzle-to-plate distances were (a) 199.9 and (b) 259.5 mm .
short to be $\mathrm{C}-\mathrm{C}$ single bonds [e.g. $\mathrm{C}(3)-\mathrm{C}(4 \mathrm{~b})=131.6(32)$, $\mathrm{C}(3 \mathrm{~b})-\mathrm{C}(4)=126.5(32), \mathrm{C}\left(3^{\prime}\right)-\mathrm{C}\left(4^{\prime} \mathrm{b}\right)=126.6(36)$ and $\left(\mathrm{C} 3^{\prime} \mathrm{b}\right)-$ $\left.\mathrm{C}\left(4^{\prime}\right)=125.5(38) \mathrm{pm}\right]$. The electron diffraction model used consists of a mixture of the axial and equatorial conformers of the trans-dibromide and provided a good fit to the diffraction pattern. Thus, from the analyses of both the single-crystal X-ray and electron diffraction patterns it is concluded that the addition of molecular bromine to 2,5-dihydrothiophene 1,1-dioxide yields the trans-dibromide.

After the first, unsatisfactory refinements of model A, a more detailed conformational study of the title compound was undertaken $a b$ initio which led to the definition of model B. Of the two $C_{2}$ symmetry minima located, the axial conformer was found to be $2.9 \mathrm{~kJ} \mathrm{~mol}^{-1}$ higher in energy at the SCF level than the equatorial one. However, inclusion of electron correlation and zero-point correction afforded essentially the same energy for both conformers, the axial form being slightly favoured by $0.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$.
In both minima, the five-membered ring adopts a twist conformation (see Fig. 5). No minimum corresponding to an envelope conformation could be located; starting from a structure with $\mathrm{S}(1)$ displaced from an otherwise planar $\mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(4) \mathrm{C}(5)$ framework (no symmetry constraints imposed), the SCF optimization led back to the equatorial twist form. (However, an envelope-like transition structure was found; see below.)

The MP2/6-31G* optimized structural parameters of the axial and equatorial conformers (Table 6) are in good agreement with those refined from the electron diffraction data and also with those of the equatorial conformer in the crystalline phase (Table 7). Only the mean $\mathrm{S}=\mathrm{O}$ and $\mathrm{S}-\mathrm{C}$ bond lengths are somewhat overestimated at the MP2/6-31G* level (146.3 and 181.7 pm , respectively), compared with the values obtained experimentally [GED: $142.5(1)$ and $179.0(3) \mathrm{pm}$, respectively]. The computations predicted that the axial and equatorial conformers should be practically isoenergetic and that they should

${ }^{a}$ Only absolute elements $\geq 50$ are included; $k_{1}$ and $k_{2}$ are scale factors.
be present in roughly equal amounts. This has indeed been found in the gas phase where the proportion of the axial form was refined to $47.2(23) \%$. In the solid state, only the equatorial conformer is present, presumably due to packing effects which preclude the crystallization of the axial form.
(a)

(c)

Fig. 5 Views of the $a b$ initio optimized geometries for (a) the equatorial conformer $\left(C_{2}\right),(b)$ the axial conformer $\left(C_{2}\right)$ and $(c)$ the transition state $\left(C_{1}\right)$ between the two minima

If the two conformers are present in solution, their interconversion is expected to be quite rapid, at least on the NMR timescale, as found generally for the dynamical behaviour of five-membered rings. ${ }^{21}$ In order to estimate the magnitude of the interconversion barrier for 3 , the transition structure (TS) between the axial and equatorial conformers was located. A first TS optimization imposing $C_{2}$ symmetry afforded a stationary point with an essentially planar $\mathrm{SC}_{4}$ framework. This, however, showed two imaginary frequencies indicating a 'hilltop' rather than a saddle-point on the potential energy surface. The true TS (one imaginary frequency) was found to possess $C_{1}$ symmetry, a slightly twisted $\mathrm{C}(2) \mathrm{C}(3) \mathrm{C}(4) \mathrm{C}(5)$ moiety ( $c a .11^{\circ}$ ), and an overall envelope conformation $\{c f$. the two CCSC dihedral
angles of $-38^{\circ}$ and $+32^{\circ}[$ Fig. $\left.5(c)]\right\}$. The computed barrier is relatively large at the $\mathrm{SCF} / 6-31 \mathrm{G}^{*}$ level, $c a .32 \mathrm{~kJ} \mathrm{~mol}^{-1}$, but is lowered substantially to $c a .17 \mathrm{~kJ} \mathrm{~mol}^{-1}$ by inclusion of electron correlation and zero point corrections. Thus, dynamic methods of NMR spectroscopy can probably not be applied to 3 in solution. ${ }^{22}$
The packing of the ( $E$ )-3,4-dibromotetrahydrothiophene 1,1 -dioxide molecules in the crystal is shown in Fig. 2. The molecules are stacked up the short $a$-axis direction and ordered with the bromine of adjacent columns close to one another [the closest intermolecular $\mathrm{Br} \cdots \mathrm{Br}$ distances are 373.8(3) pm].

Table 8 shows structural parameters for some tetrahydrothiophene 1,1 -dioxides. Although care must be exercised in comparing the results for structures with different substituents and determined by different methods, it would appear that the bond lengths and angles for $\mathrm{C}_{4} \mathrm{H}_{6} \mathrm{Br}_{2} \mathrm{SO}_{2}$ are typical of the values found for other tetrahydrothiophene 1,1 -dioxides.

## Acknowledgements

P. T. thanks the University of Edinburgh Faculty of Science and Engineering for a Chalmers Research Scholarship. M. B. thanks Professor W. Thiel and the Fonds der Chemischen Industrie for support. The calculations have been carried out on IBM RS/6000 workstations (C4 cluster) at the ETH Zürich. Electrondiffraction work was supported by the Engineering and Physical Sciences Research Council (grant no. GR/J59258), including research fellowships for P. T. B. and H. E. R., and the provision of microdensitometer facilities at the Daresbury Laboratory.
