#### Abstract

The phase transfer catalysed nucleophilic displacement of 1,3-bis(bromomethyl)benzene, 2-methoxy-5-methyl-1,3-bis(bromomethyl)benzene (2) and 1,4-bis(bromomethyl)benzene with 2-mercaptoethanol gives the respective diols 3,4 and $12(80-85 \%)$, which undergo intermolecular cyclodehydrochlorination with thiodiglycolyl dichloride and pyridine-2,6-dicarbonyl dichloride $\cdot \mathrm{HCl}$ to provide $m$-phenylene (7-10) and $p$-phenylene (13-14) based crownophanes. The single crystal X-ray structures of crownophanes 8 and 13 and their NMR studies show that the $m$-phenylene and $p$-phenylene rings remain in plane and perpendicular to the macrocyclic ring both in solution and solid phases. These crownophanes offer three soft coordinating sites ( $3 \times \mathrm{S}$ or $2 \times \mathrm{S}$ and 1 N ) conducive to complexation with $\mathrm{Ag}^{+}$and the steric restrictions imposed by $m$ - and $p$-phenylene rings restrict $2: 1(\mathrm{~L}: \mathrm{M})$ sandwich complexation required for complexation with the borderline soft $\mathrm{Pb}^{2+}$ cation. The crownophanes 7 and 9 extract $\mathrm{Ag}^{+} 172$ and 602 times, respectively, more than $\mathrm{Pb}^{2+}$.

## Introduction

The development of fast estimation, removal and separation techniques for precious and toxic silver and the use of silver complexes in photographic materials and their potential use in cancer radioimmunotherapy has drawn the attention of supramolecular chemists towards the design, synthesis and evaluation of silver selective ionophores. For designing such ionophores, the optimum requirement of 2-4 soft ( S or N ) ligating sites ${ }^{2-7}$ preorganized in a three-dimensional system has been emphasized. In the reported $\mathrm{Ag}^{+}$selective ionophores, the presence of ether units ${ }^{8-12}$ responsible for binding towards hard alkali, alkaline earth and borderline $\mathrm{Pb}^{2+}$ cations and the possibility of the formation of sandwich or polymeric complexes ${ }^{13-15}$ creating significant binding towards most soft metal ions, cause lowering of $\mathrm{Ag}^{+}$selectivities. We argued that in such hosts, the absence of hard (ether) ligating sites and the presence of stereochemical or structural features which could inhibit their sandwich or polymeric complexation requiring $>1: 1$ stoichiometric host-guest interaction could further enhance the $\mathrm{Ag}^{+}$selectivity even against the similar sized $\mathrm{Pb}^{2+}$ cation. We envisaged that to achieve such an inhibition, the crownophane designs 7-10, 13 and 14 could easily adopt the edge-on arrangement of $m$ and $p$-phenylene rings with respect to the plane of the macrocyclic ring especially during complexation. Here, we have reported the synthesis and evaluation of these ionophores and have found that $m$-phenylene derivatives $\mathbf{7}$ and $\mathbf{9}$ show a high order of selectivity for $\mathrm{Ag}^{+}$.

## Results and discussion

## Synthesis

For the synthesis of crownophanes $\mathbf{7 - 1 0}, \mathbf{1 3}$ and $\mathbf{1 4}$, the two step approach involving the reactions of appropriate dihalides with 2-mercaptoethanol to form diols (3, 4 and 12) followed by their intermolecular cyclodehydrochlorination with appropriate diacid dichlorides was adopted. The phase transfer catalysed $\left(\mathrm{K}_{2} \mathrm{CO}_{3}-\mathrm{DMF}-\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{HSO}_{4}^{-}\right)$nucleophilic displacement of 1,3-bis(bromomethyl)benzene (1) with 2-mercaptoethanol gave diol 3 ( $80 \%$ ), $m / z 258$. Similarly, reactions of 2-methoxy-5-methyl-1,3-bis(bromomethyl)benzene (2) and 1,4-bis(bromomethyl)benzene (11) with 2-mercaptoethanol under these phase transfer catalysis (PTC) conditions gave diols 4 ( $80 \%$ ), $\mathrm{m} / \mathrm{z}$

286 and $\mathbf{1 2}(85 \%), \mathrm{mp} 58^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z} 258$, respectively. The slow addition of thiodiglycolyl dichloride to a solution of $\mathbf{3}$ containing KF (anhyd.) as base and $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{HSO}_{4}{ }^{-}$as catalyst provided macrocycle $7(40 \%)$, liquid, $m / z 372$. Similarly, reactions of diols $\mathbf{4}$ and $\mathbf{1 2}$ with thiodiglycolyl dichloride under these PTC conditions gave crownophanes $\mathbf{8}(35 \%)$, mp $100^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z} 416$ and $\mathbf{1 2}(10 \%), \mathrm{mp} 62^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z} 372$, respectively. The diols $\mathbf{3}, 4$ and $\mathbf{1 2}$ failed to react with pyridine-2,6-dicarbonyl dichloride• HCl under the above PTC conditions. However, on reacting diols 3 and 12 with $\mathbf{6} \cdot \mathrm{HCl}$ by using $\mathrm{K}_{2} \mathrm{CO}_{3}$ (anhyd.) as base, the crownophanes $9(35 \%)$, mp $147^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z} 389$, and $14(25 \%)$, $\mathrm{mp} 197^{\circ} \mathrm{C}, m / z 389$, respectively, could be formed. The reaction of diol $\mathbf{4}$ with $\mathbf{6} \cdot \mathrm{HCl}$ under these conditions gave $10(35 \%)$, mp $197^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z} 433$ along with the $2: 2$ stoichiometric product $15(10 \%), \mathrm{mp} 180^{\circ} \mathrm{C}, \mathrm{m} / \mathrm{z}(\mathrm{FAB}) 867\left(\mathrm{M}^{+}+1\right)$. A $2: 2$ stoichiometric reaction might be triggered in the initial 1:1 stoichiometric intermediate by steric inhibition of the parasubstituents of the phenylene ring, in its cyclization.

## Conformational analysis

The X-ray crystal structure of crownophane $\mathbf{8}$ (Fig. 1, Table 1) shows that the $m$-phenylene ring remains in the mean plane of the macrocyclic ring. The substituent $\mathrm{O}-\mathrm{Me}$ seems to play a dominant role in determining the conformation of the macroring. The bond $\mathrm{O} 5-\mathrm{C} 18$ is almost perpendicular to the phenylene ring ( $\mathrm{C} 11-\mathrm{C} 16-\mathrm{O} 5-\mathrm{C} 18$ being $96.7^{\circ}$ ). The torsion angle $\mathrm{S} 2-\mathrm{C} 10-\mathrm{C} 11-\mathrm{C} 16$ is $86.2(3)^{\circ}$ and consequently both $\mathrm{S} 2-\mathrm{C} 10$ and $\mathrm{C} 18-\mathrm{O} 5$ bonds point towards the same side with respect to the phenylene ring (Fig. 1). To avoid steric crowding the S1-C1 bond points in a direction opposite to the C18-O5 bond, the torsion angle $\mathrm{C} 16-\mathrm{C} 15-\mathrm{C} 1-\mathrm{S} 1$ being $97.8(3)^{\circ}$. The torsion angle studies indicate that out of the four possible 1,4-thiaoxa units ( $\mathrm{O}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}$ ), three are antiperiplanar [torsion angles $\left.173.8(2)-177.1(2)^{\circ}\right]$, whereas the fourth one ( $\mathrm{O} 4-\mathrm{C} 8-\mathrm{C} 9-\mathrm{S} 3$ ) is synclinal $\left[59.7(3)^{\circ}\right]$ about the $\mathrm{C}-\mathrm{C}$ bond. The torsion angles about the $\mathrm{C}-\mathrm{O}$ bond are antiperiplanar and about the $\mathrm{C}-\mathrm{S}$ bond they are synclinal with the exception of C9-S2-C10-C11 which is antiperiplanar. In the segments $\mathrm{O} 1-\mathrm{C} 4-\mathrm{O} 2$ and $\mathrm{O} 3-\mathrm{C} 7-\mathrm{O} 4$, the carbonyl oxygens O 2 and O 4 point towards opposite sides of the macro-ring mean plane. The major difference in the conformation angles in the two halves of the macroring is that torsion angle $\mathrm{C} 2-\mathrm{S} 1-\mathrm{C} 1-\mathrm{C} 15$ is synclinal whereas

11

C9-S2-C10-C11 is antiperiplanar, which may be attributed to the steric factors. Three thioether units make a triangle with S1-S2, S2-S3 and S3-S1 placed at 7.13, 6.72 and $7.72 \AA$.

In the $p$-cyclophane based macrocycle 13 (Fig. 2, Table 1), the phenylene ring and the $-\mathrm{CH}_{2}-$ groups attached at the parapositions form one plane and the $\pi$-electron cloud of the phenylene ring is almost perpendicular to the macro-ring. Both the sulfur atoms are so oriented that the two bonds $\mathrm{C} 1-\mathrm{S} 1$ and C10-S2 are on the same side of the phenylene ring, in contrast to $m$-cyclophane where these bonds were on the opposite sides of the phenylene ring mean plane due to steric crowding caused by the OMe substituent. Out of the four 1,4-thiaoxa units, three are antiperiplanar and one (O1-C4-C5-S3) is synclinal about the $\mathrm{C}-\mathrm{C}$ bond (Fig. 2). The two carbonyl oxygens O 2 and O4 are present on opposite sides of the marco-ring mean plane, which is also observed in the case of $m$-cyclophane. The torsion angles about $\mathrm{C}-\mathrm{S}$ are all synclinal and antiperiplanar about $\mathrm{C}-\mathrm{O}$ except for $\mathrm{C} 4-\mathrm{O} 1-\mathrm{C} 3-\mathrm{C} 2$ which is synclinal. This difference in torsion angles about the $\mathrm{C}-\mathrm{O}$ bonds gives an extended conformation to one side of the macro-ring and introduces a kink at the $\mathrm{C} 2-\mathrm{C} 3$ bond. The three thioether units make a triangle with S1-S2, S2-S3 and S3-S1 placed at 7.15, 7.86 and $6.70 \AA$.

Fig. 2 ORTEP view of crownophane 13. Thermal ellipsoids are drawn with $50 \%$ probability and hydrogen atoms are drawn with arbitrary small isotopic thermal parameters for the sake of clarity.

But in the $p$-crownophane 13, $\mathrm{SCH}_{2} \mathrm{CH}_{2}(\Delta \delta-0.10), \mathrm{SCH}_{2} \mathrm{CO}$ ( $\Delta \delta-0.20$ ) and $\mathrm{OCH}_{2}(\Delta \delta-0.42)$ signals are shifted upfield, benzylic $\mathrm{CH}_{2}$ is not affected and ArH appears as a sharp 4 H singlet. This upfield shift of signals in $\mathbf{1 3}$ in comparison with $\mathbf{7}$ and $\mathbf{8}$ clearly shows that in $\mathbf{1 3}$, the $p$-phenylene ring is oriented perpendicular to the plane of the macrocycle, whereas the $m$-phenylene rings of $\mathbf{7}$ and $\mathbf{8}$ are in the plane of the crown ring. The planar $p$-phenylene ring of $\mathbf{1 2}$ does not show such an effect.

The NOESY experiments on $\mathbf{8}$ show intense cross peaks between OMe and $\mathrm{OCH}_{2}$, and between OMe and $\mathrm{SCH}_{2} \mathrm{CO}$ with cross peak intensities of 0.37 and 0.17 , respectively. These results show the proximity of $\mathrm{OCH}_{2}$ and $\mathrm{SCH}_{2} \mathrm{CO}$ units to the OMe unit and confirm the presence of an OMe group in the cavity of macrocyclic ring and thus the in-plane position of the $m$-phenylene and macrocyclic rings. Furthermore, NOESY experiments on $\mathbf{1 3}$ show the cross peaks between $\mathrm{OCH}_{2}$ and ArH , and between $\mathrm{SCH}_{2} \mathrm{CO}$ and ArH with cross peak intensities of 0.43 and 0.15 , respectively. The appearance of a singlet for ArH and their high cross peak volumes further support the perpendicular placement of the $p$-phenylene ring with respect to the macrocyclic ring. Hence, in trithiocrownophanes $\mathbf{7 , 8}$ and 13, the $m$-phenylene ring lies in plane and the $p$-phenylene ring acquires a position perpendicular to the macrocyclic ring. These results are further supported by molecular modelling.
The force field energy minimization ${ }^{17}$ by DTMM 2.0 (Fig. 3) shows that in compounds 7 and 8 , the $m$-phenylene rings remain more or less in-plane with the mean plane of the macrocyclic ring and three thioether units are directed towards the cavity resulting in a triangle with three angles at $51 \pm 0.1,62 \pm 0.5$ and $67 \pm 0.6^{\circ}$ and three S-S distances at $6.57,5.51$ and $6.23 \AA$ for 7 and $6.49,5.51$ and $6.24 \AA$ for $\mathbf{8}$ (Table 2). In the compound 13, the $p$-phenylene ring remains perpendicular to the mean plane of the macrocyclic ring. The S-S distance between two benzylic thioethers ( $7.09 \AA$ ) is much larger than the other two S-S distances ( 3.91 and $5.08 \AA$. Table 2).

Fig. 4 Overlap of energy minimized conformations (---) and X-ray crystal structure (-) for crownophanes $\mathbf{8}$ (a) and 13 (b). Graphics drawn by SHELXTL-Plus 95

It may be observed that the results of both X-ray and energy minimization studies are corroborative of in-plane and perpendicular positions of $m$-phenylene in $\mathbf{8}$ and $p$-phenylene in 13 but some contradictions are also revealed. In crownophane 8, the crystal structure reveals that $\mathrm{C} 10-\mathrm{S} 2$ and $\mathrm{O} 5-\mathrm{C} 18$ bonds lie on one side and $\mathrm{C} 1-\mathrm{S} 1$ on the opposite side of the $m$-phenylene ring, whereas energy minimizations put $\mathrm{C} 10-\mathrm{S} 2$ and $\mathrm{C} 1-\mathrm{S} 1$ in one direction. This difference in the direction of $\mathrm{C}-\mathrm{S}$ bonds causes the rest of the ring to be less extended than is observed in the X-ray structure [Fig. 4(a)]. Similarly, crownophane 13 exhibits a less extended conformation [Fig. 4(b)] by energy minimization than is observed by X-ray diffraction. These differences are not unexpected as the X-ray crystal structures are also dependent on lattice interactions and energy minimizations represent isolated molecules. However, both the studies, signifi-

cantly, lead to similar overall conformations of the phenylene rings with respect to the macrocyclic ring.

In crownophanes 9,10 and 14, the appearance of $\mathrm{OCH}_{2}$, $\mathrm{SCH}_{2}$ and $\mathrm{ArCH}_{2}{ }^{1} \mathrm{H}$ NMR signals downfield of the corresponding signals in trithioether derivatives by $0.2-0.4,0.1-0.3$ and $0.1-0.2 \mathrm{ppm}$, respectively, points to their relatively rigid nature. The comparison of the ${ }^{1} \mathrm{H}$ NMR spectrum of $1: 1$ stoichiometric product $\mathbf{1 0}$ with the $2: 2$ stoichiometric product $\mathbf{1 5}$ shows $\mathrm{ArCH}_{2}(\Delta \delta+0.09)$ and $\mathrm{SCH}_{2}(\Delta \delta+0.20)$ signals downfield in the case of $\mathbf{1 0}$ and indicates a relatively more rigid structure for $\mathbf{1 0}$ than for its dimer $\mathbf{1 5}$. In $\mathbf{1 4}$, the $\mathrm{OCH}_{2}$ signals appear upfield ( $\Delta \delta-0.16$ ) of those in 9 and $\mathbf{1 0}$. So, unlike trithioether based crownophanes 7, 8 and 13, the pyridine based crownophanes $\mathbf{9}, \mathbf{1 0}$ and $\mathbf{1 4}$ lack orderly placement of ${ }^{1} \mathrm{H}$ NMR signals and hence their conformational analysis could not be deduced from these data. However, force field energy minimizations (Fig. 3) show that in all the pyridine based macrocycles, either pyridine or the phenylene ring lies perpendicular to the plane of the macrocyclic ring. Again, in both 9 and 10, the $m$ phenylene ring lies in the plane of the macrocyclic ring and the pyridine ring is more or less perpendicular to this plane. In the case of $\mathbf{1 4}$, the pyridine ring is in the mean plane of the macrocyclic ring and the $p$-phenylene ring is perpendicular to it. Further analysis of the distances and angles between two thioether and one pyridine units shows that $\mathbf{9}, \mathbf{1 0}$ and $\mathbf{1 4}$ have similar placement of two thioether units and pyridine N with respect to each other.

## Binding characteristics

Extraction ${ }^{18}$ and transport ${ }^{19}$ studies. As the process of ligand facilitated transport of cations across a non-polar membrane has relevance to the development of separation techniques for cations, the extraction (complexation) and transport (complexation/decomplexation) profiles of macrocycles 7-10 and 13-14 towards $\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}, \mathrm{Tl}^{+}$, alkali metal cations $\left(\mathrm{Li}^{+}, \mathrm{Na}^{+}\right.$, $\mathrm{K}^{+}$) and alkaline earth cations $\left(\mathrm{Mg}^{2+}, \mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}, \mathrm{Ba}^{2+}\right)$ by using chloroform as an apolar membrane have been determined. In thioether based macrocycles, $1: 1$ and/or $2: 2$ stoichiometric complexation is facilitated in the solid phase but in the solution phase the $1: 1$ complexations are more pronounced. So for discussion of all the extraction and transport results $1: 1$ stoichiometric complexation of macrocycles with cations has been assumed.

The macrocycles 7, 8 and $\mathbf{1 3}(3 \times-$ S-) and 9, 10 and $14(2 \times$ $-\mathrm{S}-$ and PyN ) possess three soft ligating sites and two relatively non-participating ester oxygens. The discussion of the ionophore character of these macrocycles is primarily based on three soft ligating sites as, in their ${ }^{13} \mathrm{C}$ NMR titrations with $\mathrm{Ag}^{+}$, the participation of only three soft sites is evident.

These macrocycles with the exception of $\mathbf{1 4}$ show significant $\mathrm{Ag}^{+} / \mathrm{Pb}^{2+}$ extraction selectivity (Table 3, Fig. 5). The macrocycle 7 extracts 172 times more silver picrate ( $67.30 \%$ ) than $\mathrm{Pb}^{2+}$ ( $0.39 \%$ ) and $\mathbf{8}$ shows relatively enhanced extraction of both $\mathrm{Ag}^{+}(73.3 \%)$ and $\mathrm{Pb}^{2+}(0.76 \%)$ resulting in lowering of $\mathrm{Ag}^{+}$vs. $\mathrm{Pb}^{2+}$ selectivity to 98 . The alkali, alkaline earth and $\mathrm{Tl}^{+}$cations are extracted only marginally. $p$-Crownophane 3 shows lowering in both extraction of $\mathrm{Ag}^{+}(57.2 \%)$ and $\mathrm{Ag}^{+}$vs. $\mathrm{Pb}^{2+}$ selectivity. The $m$-phenylene crownophanes $\mathbf{7}$ and $\mathbf{8}$ have similar conformations, but the higher degree of extraction of $\mathrm{Ag}^{+}$and

Fig. 5 Extraction (\%) of $\mathrm{Ag}^{\mathrm{I}}$ and $\mathrm{Pb}^{\mathrm{II}}$ by crownophanes 7-10, 13 and 14
$\mathrm{Pb}^{2+}$ by $\mathbf{8}$ in comparison with 7 could be attributed to the cooperative participation of the methoxy group in complexation with cations. As expected, the methoxy unit shows better interaction with dipositive $\mathrm{Pb}^{2+}$ than monopositive $\mathrm{Ag}^{+}$and therefore $\mathrm{Ag}^{+} / \mathrm{Pb}^{2+}$ selectivity in $\mathbf{8}$ is lowered in comparison with 7. In 13, the $p$-phenylene ring places the two thioether units relatively far apart and causes lower extraction and selectivity for $\mathrm{Ag}^{+}$.
In the three-dimensional structure of the macrocycle 9 the pyridine ring is perpendicular to the $m$-phenylene ring. But PyN is placed only $5 \AA$ units away from both the thioether -S- atoms and this arrangement leads to 602 times more extraction of $\mathrm{Ag}^{+}$ $(60.28 \%)$ than $\mathrm{Pb}^{2+}(0.1 \%$, Table 3$)$. The conformation of macrocycle $\mathbf{1 0}$ is similar to that of $\mathbf{9}$, but its cavity is filled by the methoxy group. It seems that the methoxy group participates in complexation and thus macrocycle $\mathbf{1 0}$ shows increased extraction of $\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}$ and $\mathrm{Tl}^{+}$by nearly 1.4, 7.6 and 16 times, respectively, in comparison with 9 , thereby lowering the $\mathrm{Ag}^{+}$/ $\mathrm{Pb}^{2+}$ selectivity to 108 . In the macrocycle $\mathbf{1 4}$, the pyridine ring is in the plane of the macro-ring and is more available for complexation than in the case of $\mathbf{9}$ and $\mathbf{1 0}$ and shows some increase in extraction of $\mathrm{Ag}^{+}(71.61 \%)$, but extraction of $\mathrm{Pb}^{2+}$ is significantly increased to $15.2 \%$ from only $0.10 \%$ in the case of 9 . As a result, $\mathbf{1 4}$ shows only a marginal $\mathrm{Ag}^{+}$vs. $\mathrm{Pb}^{2+}$ selectivity (Fig. 5).
Amongst these designs, $m$-phenylene derivatives 7 and 9 show the highest degree of binding selectivity for $\mathrm{Ag}^{+}$though their extraction character is lower. In macrocycles 8 and 10, the possible participation of the methoxy group increases the extraction of all the cations but their three-dimensional arrays include a much more pronounced increase in the extraction of $\mathrm{Pb}^{2+}$ and $\mathrm{Tl}^{+}$, and $\mathrm{Ag}^{+}$selectivities are lowered. Furthermore, both $p$-crownophane derivatives $\mathbf{1 3}$ and $\mathbf{1 4}$ show much lower $\mathrm{Ag}^{+} / \mathrm{Pb}^{2+}$ selectivity than their $m$-phenylene counterparts 7 and 9 .
The transport rates for $\mathrm{Pb}^{2+}$ picrate could not be determined because of its significant leakage across chloroform. ${ }^{20}$ Since amongst the cations studied here, after $\mathrm{Ag}^{+}$, the most efficiently transported cation is $\mathrm{Tl}^{+}$, selectivities have been presented with respect to $\mathrm{Tl}^{+}$and for other cations these are fairly high (Table 4). The trithioether macrocycles $\mathbf{7}, \mathbf{8}$ and $\mathbf{1 3}$ transport $\mathrm{Ag}^{+}$at similar rates. But $\mathbf{8}$, in which the methoxy group can interact with $\mathrm{Tl}^{+}$, shows the lowest selectivity. Amongst pyridine based

Fig. 6 Plot of extraction (\%) vs. transport of crownophanes 7-10, 13 and 14
ionophores, 9 transports $\mathrm{Ag}^{+}$most efficiently and is the best ionophore with the highest efficiency and selectivity amongst all the six macrocycles discussed here. In parallel with the extraction results, 10 and 14 , which show highest extraction for $\mathrm{Tl}^{+}$, also show the highest transport efficiencies and lead to only marginal $\mathrm{Ag}^{+} / \mathrm{Tl}^{+}$selectivities. Furthermore, amongst all these compounds, the crownophanes $\mathbf{8}$ and $\mathbf{1 0}$ bearing methoxy units show the lowest selectivities which further confirms the more effective participation of the methoxy group in binding with cations other than $\mathrm{Ag}^{+}$. Also, the comparison of extraction and transport results of $\mathrm{Ag}^{+}$(Fig. 6) shows that with these macrocycles more than $60 \%$ extraction of $\mathrm{Ag}^{+}$leads to its lower transport rates, whereas for $\mathrm{Tl}^{+}$and other cations, the increased extraction is coupled with increased transport rates. Evidently, in the case of $\mathbf{1 0}$ and $\mathbf{1 4}$, the slower decomplexation of the more stable macrocycle $-\mathrm{Ag}^{+}$picrate complexes may be at least partially responsible for lower transport rates.

## Complexation studies through ${ }^{13} \mathrm{C}$ NMR spectroscopy

The comparison of ${ }^{13} \mathrm{C}$ NMR spectra of macrocycles with those of their $1: 1$ stoichiometric mixtures with metal picrates gives significant information about the complexation character of individual ligating sites in these macrocycles.

The $m$-phenylene crownophanes, $\mathbf{7}$ and $\mathbf{8}$, show a significant downfield shift for three $\mathrm{SCH}_{2}$ carbon signals. This shift is more pronounced in 8 , which has been found to be a better complexing agent than 7 in extraction experiments (Table 5). The participation of OMe is also evident from the downfield shift of the OMe NMR signal. The $\mathrm{OCH}_{2}$ signals also experience the effect of $\mathrm{Ag}^{+}$binding and are shifted upfield. This could be attributed to the high electron density of $\mathrm{Ag}^{+}$and its proximity to $\mathrm{OCH}_{2}$ units. In macrocycle 13, again $\mathrm{SCH}_{2}$ signals are shifted downfield but $\mathrm{OCH}_{2}$ remains almost at the same position. The analysis of the DTMM based conformation of $\mathbf{1 3}$ shows that in the $13-\mathrm{Ag}^{+}$complex, $\mathrm{Ag}^{+}$should be placed in line with $p$ phenylene thioether units and would be quite far from the $\mathrm{OCH}_{2}$.

The addition of $\mathrm{Ag}^{+}$picrate to a solution of crownophane 9 causes separation of a solid product and so NMR monitoring of the complexation could not be carried out. But in the case of 10 (Table 6), as expected, $\mathrm{SCH}_{2}$ and $\mathrm{OCH}_{3}$ signals are shifted downfield and the $\mathrm{OCH}_{2}$ signal is shifted upfield. Also, the participation of the OMe unit is more effective in $\mathbf{1 0}$ than in $\mathbf{8}$. However, due to the difficulty in differentiation of aryl and pyridine signals, the participation of pyridine could not be determined.
In conclusion, $m$-phenylene (7-10) and $p$-phenylene (13-14) based crownophanes offer three soft coordinating sites $(3 \times \mathrm{S}$ or $2 \times \mathrm{S}$ and 1 N ) conducive to complexation with $\mathrm{Ag}^{+}$and the steric restrictions imposed by $m$ - and $p$-phenylene rings restrict 2:1 (L:M) sandwich complexation required for complexation with the soft $\mathrm{Pb}^{2+}$ cation. These structural features induce high $\mathrm{Ag}^{+} / \mathrm{Pb}^{2+}$ selectivities. But in crownophanes $\mathbf{8}$ and $\mathbf{1 0}$, the presence of a hard ether ligating unit adversely affects the $\mathrm{Ag}^{+} / \mathrm{Pb}^{2+}$ selectivity.

## Experimental

Melting points were determined in capillaries and are uncorrected. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were run on a Bruker AC200 MHz instrument using TMS as an internal standard. $J$ Values are given in Hz . Mass spectra were recorded on JEOL JMSD300, VG micromass 7070 F mass spectrometers, at the Central Drug Research Institute, Lucknow, and on a Shimadzu GCMS-QP-2000 mass spectrometer at Amritsar. IR spectra were recorded on a PYE UNICAM SP3-300 IR spectrophotometer by using $\mathrm{CHCl}_{3}$ or KBr (solid) as medium. UV spectra were

recorded on a Shimadzu UV-240 spectrophotometer. Elemental analysis of solid samples was performed at the microanalytical laboratory RSIC, Chandigarh.

## Synthesis of diols 3, 4 and 12

General procedure. A solution of 1,3-bis(bromomethyl)benzene ( $\mathbf{1}$ ) ( $1.00 \mathrm{~g}, 3.7 \mathrm{mmol}$ ) and 2-mercaptoethanol $(0.74 \mathrm{~g}$, 10.11 mmol ) in DMF (dry, $50 \mathrm{~cm}^{3}$ ) containing anhydrous $\mathrm{K}_{2} \mathrm{CO}_{3}(2.65 \mathrm{~g}, 18.96 \mathrm{mmol})$ and tetrabutylammonium hydrogen sulfate $\left(\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{HSO}_{4}^{-}\right)$was stirred. After completion of the reaction (TLC, 8 h ), the solid suspension was filtered and the residue was washed with ethyl acetate $\left(10 \mathrm{~cm}^{3}\right)$. The combined filtrate was distilled under vacuum. The residue was chromatographed on a silica gel column using hexane-ethyl acetate (gradient elution $10: 1 \rightarrow 1: 1$ ) as eluents to isolate diol 3. Similarly, reaction of 1,3-bis(bromomethyl)-2-methoxy-5-methylbenzene (2) and 1,4-bis(bromomethyl)benzene (11) with 2 mercaptoethanol gave diols $\mathbf{4}$ and 12.

1,3-Bis(2-hydroxyethylthiomethyl)benzene (3) ( $80 \%$ ), liquid; $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 2.58\left(4 \mathrm{H}, \mathrm{t}, J 6.2,2 \times \mathrm{SCH}_{2}\right), 3.61(4 \mathrm{H}, \mathrm{t}, J 6.2$, $2 \times \mathrm{OCH}_{2}$ ), $3.70\left(4 \mathrm{H}, \mathrm{s}, \mathrm{SCH}_{2}\right), 7.15-7.33(4 \mathrm{H}, \mathrm{m}, \mathrm{ArH})$; $\delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right) 36.43\left(\mathrm{t}, \mathrm{SCH}_{2}\right), 41.15\left(\mathrm{t}, \mathrm{SCH}_{2}\right), 61.54\left(\mathrm{t}, \mathrm{OCH}_{2}\right)$, 127.53 (d, ArCH), 128.70 (d, ArCH), 129.25 (d, ArCH), 138.46 (s, ArC); $v_{\text {max }}(\mathrm{KBr}) / \mathrm{cm}^{-1} 3400(\mathrm{OH}) ; m / z 258\left(\mathrm{M}^{+}\right)$.

1,3-Bis(2-hydroxyethylthiomethyl)-2-methoxy-5-methyl-
benzene (4) $(80 \%)$, liquid; $\delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 2.29(3 \mathrm{H}, \mathrm{s}, \mathrm{Me}), 2.63$ $\left(4 \mathrm{H}, \mathrm{t}, J 6.0,2 \times \mathrm{SCH}_{2}\right), 3.67\left(4 \mathrm{H}, \mathrm{t}, J 6.0,2 \times \mathrm{OCH}_{2}\right), 3.72(4 \mathrm{H}$, $\left.2 \times \mathrm{SCH}_{2}\right), 3.84\left(3 \mathrm{H}, \mathrm{s}, \mathrm{OCH}_{3}\right), 7.57(2 \mathrm{H}, \mathrm{s}, \mathrm{ArH}) ; \delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right.$, DEPT-135) $20.65\left(+\mathrm{ve}, \mathrm{CH}_{3}\right), 29.61\left(-\mathrm{ve}, \mathrm{SCH}_{2}\right), 34.18$ $\left(-\mathrm{ve}, \mathrm{SCH}_{2}\right), 60.68\left(-\mathrm{ve}, \mathrm{OCH}_{2}\right), 62.35\left(+\mathrm{ve}, \mathrm{OCH}_{3}\right), 130.44$ (+ve, ArCH), 131.11 (absent, ArC), 134.01 (absent, ArC), 154.22 (absent, $\mathrm{ArC}-\mathrm{O}) ; v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} 3400(\mathrm{OH}) ; \mathrm{m} / \mathrm{z} 302$ $\left(\mathrm{M}^{+}\right)$.

1,4-Bis[(2-hydroxyethylthio)methyl]benzene (12) ( $85 \%$ ), mp $58{ }^{\circ} \mathrm{C}\left(\mathrm{CHCl}_{3}\right) ; \delta_{\mathrm{H}}\left(\mathrm{CDCl}_{3}\right) 2.62\left(4 \mathrm{H}, \mathrm{t}, J 6.0,2 \times \mathrm{SCH}_{2}\right), 3.63$ $\left(4 \mathrm{H}, \mathrm{t}, J 6.0,2 \times \mathrm{OCH}_{2}\right), 3.70\left(4 \mathrm{H}, \mathrm{s}, \mathrm{SCH}_{2}\right), 7.27(4 \mathrm{H}, \mathrm{s}, \mathrm{ArH})$; $\delta_{\mathrm{C}}\left(\mathrm{CDCl}_{3}\right.$, DEPT-135) 34.21 ( $-\mathrm{ve}, \mathrm{SCH}_{2}$ ), 41.26 ( $-\mathrm{ve}, \mathrm{SCH}_{2}$ ), 60.32 ( $-\mathrm{ve}, \mathrm{OCH}_{2}$ ), 129.11 ( $+\mathrm{ve}, \mathrm{ArCH}$ ), 137.12 (absent, ArC ); $v_{\max }(\mathrm{KBr}) / \mathrm{cm}^{-1} 3300(\mathrm{OH})$; m/z $258\left(\mathrm{M}^{+}\right)$(Found: C, 55.45 ; H, 6.87. $\mathrm{C}_{12} \mathrm{H}_{18} \mathrm{O}_{2} \mathrm{~S}_{2}$ requires $\mathrm{C}, 55.81 ; \mathrm{H}, 6.97 \%$ ).

## Synthesis of crownophanes 7, 8 and 13

General procedure. Diol 4 ( $1.00 \mathrm{~g}, 3.9 \mathrm{mmol}$ ), KF (anhyd.) and a catalytic amount of $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{HSO}_{4}^{-}(10 \mathrm{mg})$ were dissolved in dry dichloromethane $\left(100 \mathrm{~cm}^{3}\right)$ and the reaction mixture was stirred at room temperature. Thiodiglycolyl dichloride $(0.73 \mathrm{~g}$, 3.87 mmol ) dissolved in dichloromethane $\left(50 \mathrm{~cm}^{3}\right)$ was added dropwise, over 0.5 h . After completion of the reaction (TLC, 7 h ), the solid suspended was filtered off and was washed with ethyl acetate $\left(2 \times 10 \mathrm{~cm}^{3}\right)$. The combined filtrate was distilled off. The crude reaction product was chromatographed on a silica gel column using hexane-ethyl acetate (gradient elution
$10: 1 \rightarrow 1: 1)$ as eluents to isolate 9 . Similarly cyclocondensation of diols $\mathbf{5}$ and $\mathbf{7}$ with thiodiglycolyl chloride gave macrocycles 10 and 11.

## Synthesis of crownophanes 9, 10, 14 and 15

General procedure. Diol 3 ( $1 \mathrm{~g}, 3.9 \mathrm{mmol}$ ), $\mathrm{K}_{2} \mathrm{CO}_{3}$ (anhyd.) and a catalytic amount of $\mathrm{Bu}_{4} \mathrm{~N}^{+} \mathrm{HSO}_{4}^{-}(10 \mathrm{mg})$ were dissolved in dry dichloromethane $\left(100 \mathrm{~cm}^{3}\right)$ and the reaction mixture was stirred at room temperature. Pyridine-2,6-dicarbonyl dichloride $(0.73 \mathrm{~g}, 3.9 \mathrm{mmol})$ solution in dichloromethane (dry, $50 \mathrm{~cm}^{3}$ ) was added dropwise, over 0.5 h . After completion of the reaction (TLC, 7 h ), the suspension was filtered off and the solid residue was washed with ethyl acetate $\left(2 \times 10 \mathrm{~cm}^{3}\right)$. The combined filtrate was distilled off. The crude reaction product was chromatographed on a silica gel column using hexane-ethyl acetate mixtures as eluents to isolate a white compound 9 .

## X-Ray structure analysis of crownophanes 8 and 13

All intensity data measurements were carried out on a Siemens P4 four circle diffractometer with graphite monochromatic $\mathrm{Mo}-\mathrm{K} \alpha$ radiation ( $\lambda=0.71069$ Å). All structures were solved and refined using the SHELXTL software ${ }^{20}$ package on a Siemens Nixdorf computer. Crystals of $\mathbf{8}$ and $\mathbf{1 3}$ suitable for X-ray diffraction work were obtained by recrystallization from acetonitrile. The unit cell parameters were determined from a least squares fit of setting angles of 25 reflections in the range $20 \leqslant 2 \theta \leqslant 25^{\circ}$. Three standard reflections were measured every 100 reflections and showed no significant intensity variation during the data collection. The data were corrected for Lorentz and polarization effects. No absorption corrections were applied. The structures were solved by the direct methods. Full matrix least squares refinement was employed with anisotropic thermal parameters for the non-hydrogen atoms. The hydrogen atoms placed at calculated positions were refined isotropically with fixed thermal parameters and included in structure factor calculations. Crystal data and parameters for data collection and refinements are summarized in Table 7. Full crystallographic details, excluding structure factor tables, have been deposited at the Cambridge Crystallographic Data Centre (CCDC). For details of the deposition scheme, see 'Instructions for Authors', $J$. Chem. Soc., Perkin Trans. 2, available via the RSC Web page (http://www.rsc.org/authors). Any request to the CCDC for this material should quote the full literature citation and the reference number 188/121.

## Extraction measurements ${ }^{18}$

For the extraction experiments, metal picrate solutions ( 0.01 $\mathrm{mol} \mathrm{dm}{ }^{-3}$ ) were prepared in deionized distilled water. The solutions of macrocycles ( $0.01 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ ) were prepared in chloroform (AR grade).

An aqueous solution ( $2 \mathrm{~cm}^{3}$ ) of metal picrate $\left(0.01 \mathrm{~mol} \mathrm{dm}^{-3}\right)$

and a chloroform solution $\left(2 \mathrm{~cm}^{3}\right)$ of the macrocycle $(0.01 \mathrm{~mol}$ $\mathrm{dm}^{-3}$ ) were shaken in a cylindrical tube closed with a septum for 5 min and kept at $27 \pm 1^{\circ} \mathrm{C}$ for $3-4 \mathrm{~h}$. An aliquot of the chloroform layer $\left(1 \mathrm{~cm}^{3}\right)$ was withdrawn with a syringe and diluted with acetonitrile to $10 \mathrm{~cm}^{3}$. The UV absorption was measured against $\mathrm{CHCl}_{3}-\mathrm{CH}_{3} \mathrm{CN}$ (1:9) solution at 374 nm . Extraction of metal picrate has been calculated as the percentage of metal picrate extracted in the chloroform layer and the values reported here are the mean of three independent measurements which were within $\pm 2 \%$ error (Table 2).

## Transport measurements ${ }^{19}$

The transport experiments were carried out at constant temperature ( $27 \pm 1^{\circ} \mathrm{C}$ ) in a cylindrical glass cell consisting of outer and inner jackets by using (i) metal picrate ( 0.01 mol $\mathrm{dm}^{-3}$ ) in water ( $3 \mathrm{~cm}^{3}$ ) in the inner phase; (ii) water ( $10 \mathrm{~cm}^{3}$ ) in the outer phase; (iii) ligand ( $10 \mathrm{mmol} \mathrm{dm}^{-3}$ ) in a chloroform layer $\left(15 \mathrm{~cm}^{3}\right)$ with stirring ( $150 \pm 5 \mathrm{rpm}$ ) at $27 \pm 1^{\circ} \mathrm{C}$. After stirring for 6 h the picrates transported in the aqueous receiving phase were determined from the UV absorptions at 355 nm . Each value is a mean of three experiments which are consistent $\pm 10 \%$ (Table 3). Before determining the transport rates, blank experiments were performed in the absence of the carrier macrocycle in the chloroform layer to check the leakage of metal picrates. Under the conditions given for the transport experiments, in the absence of crownophanes, metal picrates (except $\mathrm{Pb}^{2+}$ picrate) are not transported to the receiving phase. However, $\mathrm{Pb}^{2+}$ picrate shows significant transport and results for crownophane induced transport of $\mathrm{Pb}^{2+}$ are not reliable and, therefore transport of $\mathrm{Pb}^{2+}$ was not determined.

## DTMM 2.0 programme ${ }^{17}$

The programme was used as provided by the company, without any further modification. The programme DTMM 2.0 uses molecular mechanistics potentials and their force fields similar to those in ref. 21. These include bond stretching potential, bong angle deformation potential, periodic torsional barrier potential and non-bonding interactions for non-bonded atom pairs. For every bond, six variables, bond length (1), bond rotation (1) and fragment orientation (4) are minimized. All variables are treated independently using a simple line search algorithm with quadratic interpolation. It provides facilities for conformational space hunting, charge calculations and hydrogen bonding.

## Acknowledgements

We thank the Department of Science and Technology, New Delhi for a research grant (SP/SI/623/92).
