# Laticyclic conjugated double bonds within the framework of oligocondensed bicyclo[2.2.2]octenes 

Wolfram Grimme, *,a Jens Wortmann, ${ }^{a}$ Dirk Frowein, ${ }^{a}$ Johann Lex, ${ }^{a}$ Grace Chen ${ }^{b}$ and Rolf Gleiter ${ }^{*, b}$<br>${ }^{a}$ Universität zu Köln, Institut für Organische Chemie, Greinstraße 4, D-50939 Köln, Germany<br>${ }^{b}$ Organisch-Chemisches Institut der Universität Heidelberg, Im Neuenheimer Feld 270, D-69120 Heidelberg, Germany

The all-syn oligocondensed bicyclo[2.2.2]octenes 3, 5, 20 and 29 with two to five etheno bridges show interaction of their $\pi$-orbitals by $\sigma$-overlap. This laticyclic conjugation reveals itself in the PE and UV spectra of the series as well as in the site selectivity of the Diels-Alder reaction with inverse electron demand found for the dehydro derivatives 11 and 26. As shown in the crystal structures of 3,5 and 20, the etheno bridges are positioned face to face at a distance which is smaller than the sum of their van der Waals radii.

## Introduction

The various ways to achieve cyclic delocalization by joining chains of conjugated $\pi$-systems were studied in 1971 by Hoffmann and Goldstein. ${ }^{1}$ One way they suggested is to arrange the chains face to face at so close a distance that $\sigma$-interaction between their termini occurs. This so-called laticyclic conjugation of unsaturated chains can result in an electronic stabilization, but it does not if all the chains are of the same mode. Accordingly, the laticyclic conjugation of ethene units leads to a set of molecular orbitals, bonding and antibonding through space, that are all filled and do not provide a net stabilisation. However, due to their filled 'antibonding' orbitals these systems should show interesting spectroscopic and chemical properties.

Rigid molecules with two double bonds facing each other in close proximity represent the simplest laticyclic conjugated systems. Many of them are known and in, for example, isodrine, ${ }^{2}$ seco-pagodadiene, ${ }^{3}$ hypostrophene, ${ }^{4}$ tricyclo[6.2.2.2 ${ }^{2,5}$ ]dodeca-1,5-diene ${ }^{5}$ and pentacyclo[8.2.1.1 $\left.{ }^{2,5} .1^{4,7} \cdot 1^{8,11}\right]$ -hexadeca-1,7-diene ${ }^{6}$ the through space interaction has been studied. We have developed a general method for the synthesis of oligocondensed bicyclo[2.2.2]octenes with all-syn configuration and here describe a series of them with up to five laticyclic conjugated etheno bridges.

## Results and discussion

The common starting compound for the synthesis of all-syn condensed bicyclo[2.2.2]octenes is endo-tetrachlorotricyclo[6.2.2.0 ${ }^{2,7}$ ]dodecatriene 1, the product of the Diels-Alder reaction of tetrachlorothiophene dioxide (TCTD) ${ }^{7}$ with dihydrobarrelene followed by $\mathrm{SO}_{2}$ extrusion. $\dagger$ The diene unit of $\mathbf{1}$ is activated for the cycloaddition with inverse electron demand ${ }^{8}$ by the chloro substituents and it reacts with unsaturated hydrocarbons if their double bond is easily accessible. This is not the case for the etheno bridge in $\mathbf{1}$ and therefore it does not add to itself. However, ethene and dihydrobarrelene undergo cycloaddition with 1 below $100^{\circ} \mathrm{C}$ under a pressure of 7 kbar (Scheme 1). The resulting condensed bicyclo[2.2.2]octenes 2 and $\mathbf{4}$ with all-syn configuration are dechlorinated with sodium in ethanol

[^0]

Scheme 1
or diethylene glycol monoethyl ether to $\mathbf{3}$ and $\mathbf{5}$ without the reduction of double bonds. This result differs from that obtained when $\pi$-conjugated polyenes bearing chloro substituents are submitted to the same conditions. The triene $\mathbf{1}$ for example is dechlorinated with loss of a conjugated double bond by sodium in ethanol. The empty antibonding MOs of the $\pi$-conjugated diene are responsible for this overreduction.

This route to syn-oligocondensed bicyclo[2.2.2]octenes with laticyclic conjugated etheno bridges was pursued further by using dienophiles with an extended bicyclo[2.2.2]octadiene unit. For the preparation of the next higher homologue with four etheno bridges syn-dehydrosesquibicyclo[2.2.2]octene $\mathbf{1 1}$ was needed as a dienophile. It was synthesized from the cycloadduct $6^{9}$ of $p$-benzoquinone to cyclohexadiene in which the carbonyl flanked double bond was saturated with zinc in acetic acid (Scheme 2). The resulting diketone 7 was transformed into tricyclo[6.2.2.0 ${ }^{2,7}$ ]dodeca-3,6,9-triene 9 via the Shapiro reaction ${ }^{10}$ of its bis(tosylhydrazone) 8. Cycloaddition of the acetylene synthon $(E)$-1,2-ditosylethene ${ }^{11,12}$ to 9 occurs to the convex side to give $\mathbf{1 0}$ which was detosylated with sodium amalgam to the triene $\mathbf{1 1}$.

Scheme 2

To synthesize the four-fold syn-condensed bicyclo[2.2.2]octene we planned to add two molecules of the diene $\mathbf{1}$ to barrelene $16^{13}$ as the central unit. On our route to barrelene ${ }^{14}$ we added in the first step $(E)$-1,2-ditosylethene to dimethyldioxabicyclo[4.3.0]nonadiene ${ }^{15}$ to give 12. After forming the second double bond in the bicyclo[2.2.2]octadiene unit by detosylation with sodium amalgam, the acetonide $\mathbf{1 3}$ was hydrolyzed and the resulting diol $\mathbf{1 4}$ mesylated. Demesylation ${ }^{16}$ of $\mathbf{1 5}$ with sodium anthracenide ${ }^{17}$ afforded barrelene 16 in a reasonable overall yield.

The cycloaddition of diene $\mathbf{1}$ to syn-dehydrosesquibicyclo[2.2.2]octene $\mathbf{1 1}$ cannot be as straightforward as in the case of dihydrobarrelene since the two accessible double bonds in $\mathbf{1 1}$ have different surroundings. The reaction under high pressure yielded a mixture of two isomers $\mathbf{1 7}$ and $\mathbf{1 9}$ (Scheme 3) with the angular adduct prevailing in a ratio of $3: 1$. This result can be rationalized by the laticyclic conjugation in $\mathbf{1 1}$ that enriches one of the double bonds of the bicyclo[2.2.2]octadiene subunit with electrons and favors its addition to the electron poor diene 1. Both cycloadditions occur exclusively to the convex side of 1 with endo stereochemistry. After separation by liquid chromatography, both cycloadducts were dechlorinated with sodium in diethylene glycol monoethyl ether to the tetraenes 18 and 20, respectively.

The electron poor diene TCTD also discriminates between the two accessible double bonds of 11, forming at room temperature two isomeric cycloadducts. The main product is the tetrachlorobenzo-condensed tetracyclic diene 21 (59\%), that results from cycloaddition to the laticyclic conjugated double bond of $\mathbf{1 1}$ followed by extrusion of $\mathrm{SO}_{2}$ and a dyotropic hydrogen shift. ${ }^{18}$ The minor product $22(27 \%)$ is a homologue of the tetrachlorodiene 1. It adds dihydrobarrelene under high pressure to give the laticyclic conjugated tetraene 19 in good yield. This alternative route to 19 offers no advantage as it again includes the addition of an electron poor diene to the wrong double bond of $\mathbf{1 1}$.

In contrast to the all-syn-condensed bicyclo[2.2.2]octenes 3, 5 and 20 that are thermally stable up to $280^{\circ} \mathrm{C}$ the angular tetraene $\mathbf{1 8}$ decomposes at $214{ }^{\circ} \mathrm{C}$ to bicyclo[2.2.2]octene 24, naphthalene, benzene and ethene (Scheme 4). Monitoring the reaction by sealed-tube NMR showed that the products are formed simultaneously in equal amounts. A proposed mechanism for this fragmentation starts with an intramolecular hydrogen transfer ${ }^{19}$ in $\mathbf{1 8}$ converting it into its dyotropomer 23. A rapid cascade of three $(4+2)$-cycloreversions then splits 23

Scheme 3

Scheme 4
into the observed products with benzodehydrosesquibicyclo[2.2.2]octene $\mathbf{2 5}$ and dihydrobarrelene as intermediates.
The two-fold cycloaddition of $\mathbf{1}$ to barrelene at $110^{\circ} \mathrm{C}$ and 8.1 kbar over 120 h led to the angular and the linear tetracondensed bicyclo[2.2.2]octenes 27 and $\mathbf{2 8}$ in a ratio of 1:3.5 (Scheme 5). The monoadduct 26 formed in the first step is a higher homologue of $\mathbf{1 1}$ and again provides a laticyclic conjugated and a terminal double bond for the second addition of the electron poor diene 1. In this case, however, the terminal double bond is preferred since the four chloro substituents withdraw electrons from the laticyclic system. Dechlorination of the linear tetracondensed bicyclo[2.2.2]octene $\mathbf{2 8}$ to $\mathbf{2 9}$ was achieved with sodium in diethylene glycol monoethyl ether.

Scheme 5

Fig. 1 Computer generated crystal structure (hydrogen atoms omitted) of all-syn-condensed bicyclo[2.2.2]octenes $\mathbf{3}, \mathbf{5}$ and 20. Parameters given are from X-ray structural analysis (in bold type) and from calculations at the B3LYP/6-31G* (in normal type) and RHF 6-31G* (in italics) level.

X-Ray structure analyses were performed for the polyenes $\mathbf{3}$, 5 and $\mathbf{2 0}$ with two to four etheno bridges. They show that their $\sigma$-framework is not linear but forms an arc. The etheno bridges face each other more closely than is expected from the sum of their van der Waals radii. The contact between the inner pair of $\mathbf{2 0}$ is a little closer ( $3.04 \AA$ ) than that to the terminal bridges ( $3.08 \AA$ ), but compared to the bond alternation in $\pi$-conjugated chains the distance between the $\sigma$-conjugated

Table 1 Vertical ionization energies $E_{\mathrm{i}, \mathrm{v}, j}$ of oligocondensed bicyclo[2.2.2]octenes and calculated orbital energies, $-\varepsilon_{j}$, using the AM1 and RHF $\left(6-31 \mathrm{G}^{*}\right)$ basis. All values in eV .

| Compound | Band | $E_{\mathrm{i}, \mathrm{v}, j}$ | Assignment | $-\varepsilon_{j}(\mathrm{AM} 1)$ | $-\varepsilon_{j}(\mathrm{RHF})$ |
| :--- | :--- | :--- | :--- | :--- | :---: |

|  | 3 | 9.2 | $\mathrm{~b}_{1}(\pi)$ |  | 9.56 |

double bonds shows little variation. As the four localised $\pi$-orbitals are filled and the same is true for the four laticyclic orbitals resulting from their linear combination, the bond order between the etheno bridges is zero. The laticyclic system thus would drift apart were it not kept together by the rigid $\sigma$-framework.
In order to assign the ionization potentials of the laticyclic conjugated polyenes we carried out $a b$ initio ${ }^{20}$ studies on the compounds $\mathbf{3}, \mathbf{5}$ and 20. Calculations were performed with the program GAUSSIAN94 ${ }^{21}$ on IBM RISC-6000 Model 580. Molecules 3, $\mathbf{5}$ and $\mathbf{2 0}$ were fully optimized within $C_{2 \mathrm{v}}$ symmetry constraint using restricted Hartree-Fock theory (RHF) and density functional theory (DFT) ${ }^{22}$ applying the hybrid method Becke3LYP ${ }^{23}$ together with the $6-31 \mathrm{G}^{*}$ basis set. All structures were confirmed to be minima by analytical vibrational frequency calculations.
The optimized structures of $\mathbf{3}, \mathbf{5}$ and 20, together with important structural parameters, are shown in Fig. 1. In general, they agree very well with the corresponding X-ray structures. At the RHF/6-31G* level, all ethene- and $\sigma$-bond lengths differ from the corresponding data in the X-ray structures by less than $0.15 \AA$. All structures show that the $\sigma$ framework forms an arc and, furthermore, the degree of bending grows with the number of condensed bicyclo[2.2.2]octene units. The distances between the etheno bridges decrease with the chain getting longer. The calculated contact between the etheno bridges is $3.14 \AA$ in $3,3.12 \AA$ in 5 and 3.10 and 3.12 $\AA$ in 20. As found in the X-ray structure, for compound 20 the contact of the inner pair is predicted to be closer than that of the terminal bridges.
The presence of laticyclic conjugation in the all-syncondensed bicyclo[2.2.2]octenes is demonstrated by their PE spectra. In Table 1 the ionization energies of $\mathbf{3}, 5$ and $\mathbf{2 0}$ are listed together with the assignment of the individual bands. The latter is based on the results of semi-empirical (AM1) ${ }^{24}$ and $a b$ initio (RHF/6-31G*) calculations on the ground state assuming the validity of Koopmans' theorem. ${ }^{25}$ The first ionization energies decrease from 9.05 eV in the parent bicyclo[2.2.2]octene $24^{26}$ to 7.4 eV in its three-fold condensed homologue 20. The second ionization energies also decrease from 9.4 eV in $\mathbf{3}$ to 8.3 eV in $\mathbf{2 0}$ as does the splitting between the two upmost laticyclic MOs. Semi-empirical (AM1) and ab initio (RHF/6-31G*) calculations indicate that all the $\pi$-MOs of the all-syn oligocondensed bicyclo[2.2.2]octenes result from laticyclic conjugation. A detailed analysis by means of the Weinhold natural bond orbital localization procedure ${ }^{27}$ applying the method of Imamura and Ohsaku ${ }^{28}$ shows large through space interactions and very little through bond contributions. The symmetry of the laticyclic HOMOs and HOMOs-1 in 3, 5 and 20 is the same as that familiar from the two upmost $\pi$-MOs in ethene, the allylic triad and butadiene (Fig. 2).
The UV spectra of the series of all-syn oligocondensed bicyclo[2.2.2]octenes show a continuous bathochromic shift of their long wavelength absorption from $\lambda_{\max }=220 \mathrm{~nm}$ for 3 to $\lambda_{\text {max }}=250 \mathrm{~nm}$ for 29 with a broad end absorption (Fig. 3).

Fig. 2 Orbital symmetry of laticyclic conjugated oligocondensed bicyclo[2.2.2]octenes and of $\pi$-conjugated open chains. The HOMO and HOMO-1 of $\mathbf{3}, \mathbf{5}$ and $\mathbf{2 0}$ are compared with the two upmost $\pi$-MOs of ethene, the allylic triad and butadiene.

Fig. 3 UV absorption spectra of all-syn oligocondensed bicyclo[2.2.2] octenes in $n$-hexane

Additionally, the higher homologues exhibit a second band at shorter wavelengths. In comparison with $\pi$-conjugated open chain polyenes ${ }^{29}$ the laticyclic systems absorb at lower wavelengths and with extinction coefficients that are smaller by two orders of magnitude. The complete occupation of all laticyclic orbitals resulting from the interaction of the bonding ethene MOs accounts for this effect.

In conclusion, the structural, spectroscopic and chemical properties of the all-syn oligocondensed bicyclo[2.2.2]octenes with two to five etheno bridges indicate the presence of laticyclic conjugation. The $\pi$-electron configuration of these systems results from perturbation theory in the same way as it does for chains of $\pi$-conjugated p -atomic orbitals (AOs). However, in the latter the interaction of singly occupied AOs affords resonance stabilisation whereas the laticyclic interaction of filled $\pi$-MOs destabilizes the system.

## Experimental

NMR spectra were recorded on a Bruker AM 300 spectrometer at $300 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right)$ and $75.5 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$ in $\mathrm{CDCl}_{3}$. Chemical shifts are in ppm relative to internal TMS. Signals were assigned by C-H COSY and NOE methods. Multiplicity and position of protons are abbreviated as follows: $\mathrm{AA}^{\prime}, \mathrm{BB}^{\prime}$ (part of $\mathrm{AA}^{\prime} \mathrm{BB}^{\prime}$ system at low, high field); AB ( AB system centered at the position given); $\Delta v$ (shift difference of the nuclei of the AB system in Hz ); $J$ (coupling constant between the nuclei of the AB system in Hz ); $\mathrm{H}_{\mathrm{n}}, \mathrm{H}_{\mathrm{x}}$ (hydrogen atoms in the endo- or exo-position). UV spectra were obtained using a Perkin-Elmer Lambda 7 spectrometer, IR spectra were recorded on a Perkin-Elmer 1600 FTIR spectrometer, mass
spectra on a Finnigan MAT INCOS 50 spectrometer. For preparative GC a Varian Aerograph 90 P was used. Reactions under high pressure were performed in a 10 ml steel autoclave (Nova Swiss, Neu-Isenburg) shielded by a heavy plastic case and heated with an electrical coil. The two stage pressure generator is a product of B. Dieckers, Krefeld. The reaction mixture was sealed into a polytetrafluoroethene (PTFE) cramping tube ( $10 \mathrm{~cm}, 0.6 \mathrm{~cm}$ diameter). Melting points were determined in open capillaries with a Tottoli apparatus (Büchi, Flawil). For flash chromatography Silitech 32-64 60A (ICN, Eschwege) was used in a column ( $50 \times 3 \mathrm{~cm}$ ) filled to a third of its height.
endo-3,4,5,6-Tetrachlorobicyclo[6.2.2.0 ${ }^{2,7}$ ]dodeca-3,4,9-triene 1
Dihydrobarrelene ( $354 \mathrm{mg}, 3.34 \mathrm{mmol}$ ) in benzene ( 2 ml ) was added at room temperature to freshly sublimed tetrachlorothiophene dioxide (TCTD, $848 \mathrm{mg}, 3.34 \mathrm{mmol}$ ). The exothermic reaction that evolves $\mathrm{SO}_{2}$ was finished by stirring for 1 h . The mixture was evaporated and the residue in hexane was filtered through silica gel $(1 \mathrm{~cm})$. Concentration in a rotary evaporator yielded 1 ( $982 \mathrm{mg}, 99^{\circ} \%$ ), $\mathrm{mp} 96-97^{\circ} \mathrm{C}$; $\delta_{\mathrm{H}} 1.31(2 \mathrm{H}$, $\left.\mathrm{BB}^{\prime}, 11-\mathrm{H}_{\mathrm{n}}, 12-\mathrm{H}_{\mathrm{n}}\right), 1.33\left(2 \mathrm{H}, \mathrm{AA}^{\prime}, 11-\mathrm{H}_{\mathrm{n}}, 12-\mathrm{H}_{\mathrm{n}}\right), 3.13(2 \mathrm{H}$, s, 2-H, 7-H), $3.21(2 \mathrm{H}, \mathrm{t}, 1-\mathrm{H}, 8-\mathrm{H}), 6.32(2 \mathrm{H}, \mathrm{q}, 9-\mathrm{H}, 10-\mathrm{H})$; $\delta_{\mathrm{C}} 24.08,33.68,48.39,123.03,132.60,133.94 ; \lambda_{\max }($ hexane $) / \mathrm{nm}$ $280\left(\varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} 2500\right)$, 292 (5300), 304 (6300), 318 (4400).
syn-3,4,5,6-Tetrachlorotetracyclo[6.2.2.2. ${ }^{3,6} \mathbf{0}^{2,7}$ ]tetradeca-4,9diene 2
$\mathbf{1}(296 \mathrm{mg}, 1 \mathrm{mmol})$ in diethyl ether ( 25 ml ) was filled into the glass liner of an autoclave $(50 \mathrm{ml})$. After fitting the vessel with a stopper with a gas inlet and a gas outlet tube it was cooled to $-100^{\circ} \mathrm{C}$ and ethene ( 800 ml ) was condensed into the solution. The glass liner was placed into the cooled (dry ice) steel autoclave which was closed and heated to $130^{\circ} \mathrm{C}$ for 90 h . After cooling to room temperature excess ethene was released and the reaction mixture was concentrated and recrystallized from hexane to afford $2(310 \mathrm{mg}, 95 \%), \mathrm{mp} 84^{\circ} \mathrm{C}$; (Found C, 51.89; H, 4.67. Calc. for $\left.\mathrm{C}_{14} \mathrm{H}_{14} \mathrm{Cl}_{4}: \mathrm{C}, 51.89 ; \mathrm{H}, 4.35\right) ; \lambda_{\max }{ }^{-}$ (hexane) $/ \mathrm{nm} 222 \mathrm{sh}\left(\varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} 2200\right.$ ); $v_{\max } / \mathrm{cm}^{-1} 3052$, 2950, 2918, 2902, 2870, 2860, 1595; $\delta_{\mathrm{H}} 1.19-1.24(2 \mathrm{H}, \mathrm{m}$, $11-\mathrm{H}_{\mathrm{n}}, 12-\mathrm{H}_{\mathrm{n}}$ ), 1.44-1.51 ( $2 \mathrm{H}, \mathrm{m}, 11-\mathrm{H}_{\mathrm{x}}, 12-\mathrm{H}_{\mathrm{x}}$ ), $1.90-1.96$ $\left(2 \mathrm{H}, \mathrm{m}, 13-\mathrm{H}_{\mathrm{n}}, 14-\mathrm{H}_{\mathrm{n}}\right), 2.10-2.16\left(2 \mathrm{H}, \mathrm{m}, 13-\mathrm{H}_{\mathrm{x}}, 14-\mathrm{H}_{\mathrm{x}}\right)$, 2.36 ( $2 \mathrm{H}, \mathrm{s}, 2-\mathrm{H}, 7-\mathrm{H}$ ), $2.90(2 \mathrm{H}, \mathrm{m}, 1-\mathrm{H}, 8-\mathrm{H}), 6.01-$ 6.03 ( $2 \mathrm{H}, \mathrm{m}, 9-\mathrm{H}, 10-\mathrm{H}$ ); $\delta_{\mathrm{C}} 25.39$ (C-11, 12), 31.65 (C-1, 8), 38.87 (C-13, 14), 52.81 (C-2, 7), 70.74 (C-3, 6), 127.35 (C-4, 5), 129.60 (C-9, 10); $m / z 287$ ( $100 \%, \mathrm{M}-\mathrm{Cl}$ ), 251 ( $82, \mathrm{M}-$ $\mathrm{Cl}-\mathrm{HCl})$.

## syn-Tetracyclo[6.2.2.2 $\left.{ }^{3,6} .0^{2,7}\right]$ tetradeca-4,9-diene 3

A solution of $\mathbf{2}(130 \mathrm{mg}, 0.4 \mathrm{mmol})$ in anhydrous ethanol ( 8 ml ) was heated to reflux under an argon atmosphere. Sodium $(460 \mathrm{mg}, 20 \mathrm{mmol})$ in small pieces was added over 2.5 h to the stirred solution and heating was continued for a further 30 min . After cooling to room temperature the reaction slurry was poured on a mixture of ice and water ( 20 g ) and extracted with hexane $(3 \times 30 \mathrm{ml})$. The combined organic layers were washed with water $(2 \times 30 \mathrm{ml})$ and brine $(1 \times 30 \mathrm{ml})$ and dried over $\mathrm{MgSO}_{4}$. The crude product was purified by flash chromatography on silica gel (hexane) and recrystallized from hexane to yield $3(52.1 \mathrm{mg}, 70 \%), \mathrm{mp} 56^{\circ} \mathrm{C}$; $\lambda_{\text {max }}$ (hexane) $/ \mathrm{nm} 220$ $\left(\varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} 1150\right) ; v_{\max } / \mathrm{cm}^{-1} 3042$, 3034, 2973, 2933, 2899, 2875, 2860, 1648, 688; $\delta_{\mathrm{H}} 1.05-1.09\left(4 \mathrm{H}, \mathrm{m}, 11-\mathrm{H}_{\mathrm{n}}\right.$, $\left.12-\mathrm{H}_{\mathrm{n}}, 13-\mathrm{H}_{\mathrm{n}}, 14-\mathrm{H}_{\mathrm{n}}\right), 1.43-1.51\left(4 \mathrm{H}, \mathrm{m}, 11-\mathrm{H}_{\mathrm{x}}, 12-\mathrm{H}_{\mathrm{x}}, 13-\mathrm{H}_{\mathrm{x}}\right.$, $\left.14-\mathrm{H}_{\mathrm{x}}\right), 1.93(2 \mathrm{H}, \mathrm{s}, 2-\mathrm{H}, 7-\mathrm{H}), 2.28(4 \mathrm{H}, \mathrm{m}, 1-\mathrm{H}, 3-\mathrm{H}, 6-\mathrm{H}$, $8-\mathrm{H}), 5.74-5.77(4 \mathrm{H}, \mathrm{m}, 4-\mathrm{H}, 5-\mathrm{H}, 9-\mathrm{H}, 10-\mathrm{H}) ; \delta_{\mathrm{C}} 27.12(\mathrm{C}-11$, 12, 13, 14), 35.15 (C-1, 3, 6, 8), 43.69 (C-2, 7), 131.96 (C-4, 5, 9, 10); m/z $186\left(\mathrm{M}^{+}, 44 \%\right), 106\left(18, \mathrm{M}-\mathrm{C}_{6} \mathrm{H}_{8}\right), 80(100$, $\left.\mathrm{C}_{6} \mathrm{H}_{8}{ }^{+}\right), 78\left(24, \mathrm{C}_{6} \mathrm{H}_{6}{ }^{+}\right)$; Calc. for $\mathrm{C}_{14} \mathrm{H}_{18}: 186.141$, Found 186.140 (MS).
all-syn-1,8,15,16-Tetrachlorohexacyclo[6.6.2.2 $\left.2^{3,6} \cdot 2^{10,13} \cdot 0^{2,7} \cdot 0^{9,14}\right]$ -icosa-4,11,15-triene 4
A solution of $1(424 \mathrm{mg}, 1.43 \mathrm{mmol})$ and bicyclo[2.2.2]octa-2,5-diene ( $152 \mathrm{mg}, 1.43 \mathrm{mmol}$ ) in anhydrous tetrahydrofuran (THF, 1.5 ml ) together with a crystal of 4-tert-butylcatechol was heated for 96 h to $80^{\circ} \mathrm{C}$ under a pressure of 7.8 kbar . After cooling to room temperature the solvent was removed under vacuum and the product purified by flash chromatography on silica gel (hexane) and recrystallized from hexane. 4 ( 486 mg , $85 \%$ ), mp $198^{\circ} \mathrm{C}$ (dec.) A solution of $28(240 \mathrm{mg}, 0.35 \mathrm{mmol})$ in diethylene glycol monoethyl ether $(150 \mathrm{ml})$ was prepared at $110^{\circ} \mathrm{C}$ under an argon atmosphere. To the stirred solution sodium $(1.6 \mathrm{~g}, 70$ mmol) was added in small pieces over 5 h . Heating was continued for a further 15 min and the cooled reaction mixture was poured on water $(100 \mathrm{ml})$. The precipitate was collected on silica gel $(50 \mathrm{mg})$ by filtration. The silica gel was washed thoroughly with water and a small amount of methanol and continuously extracted with boiling hexane. After 4 d the extract was concentrated and the residue recrystallized from $\mathrm{CHCl}_{3} .29(36.8 \mathrm{mg}, 25 \%), \operatorname{mp~} 305^{\circ} \mathrm{C}$ (dec.); $\lambda_{\text {max }}(n$-hexane) $/ \mathrm{nm}$ 214sh ( $\varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1} 3800$ ), 250 (1020); $v_{\text {max }} / \mathrm{cm}^{-1}(\mathrm{KBr})$ 3047, 2918, 2906, 2883, 2875, 684; $\delta_{\mathrm{H}}\left(\mathrm{C}_{6} \mathrm{D}_{6}, 70^{\circ} \mathrm{C}\right) 1.15(4 \mathrm{H}$, $\mathrm{BB}^{\prime}, \mathrm{H}_{\mathrm{n}}$ on $\left.\mathrm{CH}_{2}\right), 1.48\left(4 \mathrm{H}, \mathrm{AA}^{\prime}, \mathrm{H}_{\mathrm{x}}\right.$ on $\left.\mathrm{CH}_{2}\right), 1.89(8 \mathrm{H}, \mathrm{m}$, $2-\mathrm{H}, 4-\mathrm{H}, 9-\mathrm{H}, 11-\mathrm{H}, 13-\mathrm{H}, 15-\mathrm{H}, 20-\mathrm{H}, 22-\mathrm{H}), 2.16(6 \mathrm{H}, \mathrm{m}$, $1-\mathrm{H}, 3-\mathrm{H}, 10-\mathrm{H}, 12-\mathrm{H}, 14-\mathrm{H}, 21-\mathrm{H}), 2.21(4 \mathrm{H}, \mathrm{m}, 5-\mathrm{H}, 8-\mathrm{H}$, $16-\mathrm{H}, 19-\mathrm{H}), 5.19(2 \mathrm{H}, \mathrm{m}, 23-\mathrm{H}, 24-\mathrm{H}), 5.23(4 \mathrm{H}, \mathrm{m}, 25-\mathrm{H}$, $26-\mathrm{H}, 27-\mathrm{H}, 28-\mathrm{H}), 5.72(4 \mathrm{H}, \mathrm{m}, 6-\mathrm{H}, 7-\mathrm{H}, 17-\mathrm{H}, 18-\mathrm{H})$; $m / z 420\left(\mathrm{M}^{+}, 5 \%\right), 91\left(55, \mathrm{C}_{7} \mathrm{H}_{7}{ }^{+}\right), 80\left(85, \mathrm{C}_{6} \mathrm{H}_{8}{ }^{+}\right), 79(100$, $\left.\mathrm{C}_{6} \mathrm{H}_{7}^{+}\right), 78\left(90, \mathrm{C}_{6} \mathrm{H}_{6}^{+}\right)$.

## Crystal data

3: $\mathrm{C}_{14} \mathrm{H}_{18}, \quad M=186.28$. Triclinic, $\quad a=6.268(1), \quad b=8.387(1)$, $c=11.135(1) \AA, \quad \alpha=109.09(1), \quad \beta=90.24(1), \quad \gamma=111.68(1)^{\circ}$, $V=518.91(11) \AA^{3}$ (by least-squares refinement on diffractometer angles for 25 automatically centered reflections, $\lambda=$ $0.71069 \AA$ ), space group $P \overline{1}, Z=2, D_{\mathrm{x}}=1.192 \mathrm{~g} \mathrm{~cm}^{-3}$. Crystal dimensions: $0.25 \times 0.25 \times 0.03 \mathrm{~mm}, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=0.96 \mathrm{~cm}^{-1}$.

5: $\mathrm{C}_{20} \mathrm{H}_{24}, M=264.39$. Triclinic, $a=6.376(1), b=10.376(1)$, $c=11.232(1) \AA, \alpha=97.99(2), \beta=90.81(2), \gamma=107.30(2)^{\circ}, \quad V=$ 701.01(14) $\AA^{3}$ (by least-squares refinement on diffractometer angles for 25 automatically centered reflections, $\lambda=0.71069 \AA$ ), space group $P \overline{1}, Z=2, D_{\mathrm{x}}=1.253 \mathrm{~g} \mathrm{~cm}^{-3}$. Crystal dimensions: $0.30 \times 0.30 \times 0.20 \mathrm{~mm}$.

20: $\mathrm{C}_{26} \mathrm{H}_{30}, M=342.50$. Triclinic, $a=6.385(2), b=6.398(2)$, $c=24.947(6) ~ \AA, \quad a=86.11(2), \quad \beta=86.76(2), \quad \gamma=60.27(2)^{\circ}$, $V=882.7(4) \AA^{3}$ (by least-squares refinement on diffractometer angles for 25 automatically centered reflections, $\lambda=0.71069 \AA$ ), space group $P \overline{1}, Z=2, D_{\mathrm{x}}=1.289 \mathrm{~g} \mathrm{~cm}^{-3}$. Crystal dimensions: $0.15 \times 0.20 \times 0.22 \mathrm{~mm}$.

## Data collection

CAD4 diffractometer, $\omega / 2 \delta$ mode with $\omega$ scan width $=$
$0.70+0.35 \tan \theta, \omega$ scan speed $2.2 \mathrm{deg} \min ^{-1}$, graphite-monochromated $\mathrm{Mo}-\mathrm{K} \alpha$ radiation. 3: 2257 reflections measured ( $2<\theta<27^{\circ}$ ), giving 1579 with $I>2 \sigma(I) ; 5: 4070$ reflections measured ( $2<\theta<27^{\circ}$ ), giving 3365 with $I>2 \sigma(I) ; 20: 4943$ reflections measured ( $2<\theta<28^{\circ}$ ), giving 2523 with $I>2 \sigma(I)$. Linear and approx. isotropic crystal decay, ca $1.6 \%$ corrected during processing.

## Structure analysis and refinement

After data reduction, the structure was solved by direct methods using the MolEN program package and refined against $F_{0}{ }^{2}$ for all unique reflections using SHELXL-93 ${ }^{30}$ ( C atoms with anisotropic temperature factors and H atoms with isotropic ones). Final $R_{1}$ and $w R_{2}$ values for reflections $I>2 \sigma(I)$ are 3: $R_{1}=0.056$ and $w R_{2}=0.123 ; 5: \quad R_{1}=0.045$ and $w R_{2}=0.118 ; 20: \quad R_{1}=0.062$ and $w R_{2}=0.159 ; \quad R_{1}=$ $\left[\Sigma\left|\left|F_{\mathrm{o}}\right|-\left|F_{\mathrm{c}}\right| / \Sigma\right| F_{\mathrm{o}} \mid\right], w R_{2}=\left\{\left[\Sigma w\left(F_{\mathrm{o}}^{2}-F_{\mathrm{c}}^{2}\right)^{2} /\left[\Sigma w\left(F_{\mathrm{o}}^{2}\right)^{2}\right]\right\}^{\frac{1}{2}}\right.$; weighting scheme 3: $w=1 /\left[\sigma^{2}\left(F_{0}{ }^{2}\right)+(0.053 P)^{2}+0.162 P\right] ; \mathbf{5}: w=1 /$ $\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.069 P)^{2}+0.109 P\right] ; 20: w=1 /\left[\sigma^{2}\left(F_{\mathrm{o}}{ }^{2}\right)+(0.094\right.$ $\left.P)^{2}+0.737 P\right]$; where $P=\left(F_{\mathrm{o}}{ }^{2}+2 F_{\mathrm{c}}{ }^{2}\right) / 3$. The calculations were performed at the Regional Computational Center at the University of Cologne. Full crystallographic details, excluding structure factor tables, have been deposited at the Cambridge Crystallographic Data Center (CCDC). For details of the deposition scheme, see 'Instructions for Authors', J. Chem. Soc., Perkin Trans. 2, available via the RSC web page (http:// www.rsc.org/authors). Any request to the CCDC for this material should quote the full literature citation and the reference number 188/136.

## Photoelectron spectra

The $\mathrm{He}(\mathrm{I})$ photoelectron spectra of $\mathbf{3 , 5}$ and $\mathbf{2 0}$ were recorded on a Perkin-Elmer PS18 spectrometer. The recording temperatures were as follows: 3: $40^{\circ} \mathrm{C}, \mathbf{5 :} 125^{\circ} \mathrm{C}, \mathbf{2 0}: 160^{\circ} \mathrm{C}$. The calibration was performed with $\operatorname{Ar}$ ( 15.76 and 15.94 eV ) and $\mathrm{Xe}(12.13$ and 13.44 eV$)$. A resolution of 20 meV on the ${ }^{3} \mathrm{P}_{3 / 2}$ line was obtained.

## Acknowledgements

Financial support by the Deutsche Forschungsgemeinschaft is gratefully acknowledged. R. G. thanks the Fonds der Chemischen Industrie for support, G. C. thanks the Alexander von Humboldt Foundation for a stipend. We are grateful to Alexander Flatow for recording the $\mathrm{He}(\mathrm{I})$ photoelectron spectra.

[^0]:    $\dagger$ The term syn indicates that the functional groups, here double bonds, are orientated towards each other. Our linear oligocondensed bicyclo[2.2.2]octenes are all-syn; in their angular isomers the double bonds facing each other are marked by numbers, e.g. tetraene 17 is 15,16 ; 19,20;21,22-syn. The term endo refers to the configuration of DielsAlder products with the 'maximum accumulation of unsaturation'.
