Received (in Cambridge) 24th August 1998, Accepted 15th December 1998

5,15-cis-Bis(2-trifluoroacetamidophenyl)porphyrin 2c and its pentafluorobenzamidophenyl analogue 2e have significant recognising ability for $p$-benzoquinone 3a, which is explained by the large negative enthalpy change of the $\mathbf{2 c} \mathbf{c} \mathbf{- 3 a}$ complex and by the small entropy change of the $\mathbf{2 e}-\mathbf{3 a}$ complex, respectively. Porphyrin $\mathbf{2 e}$ recognises electron-rich $p$-benzoquinone more effectively than electron-deficient $p$-benzoquinone, which is ascribed to the enthalpy change of the complexation induced by the hydrogen bonding of amide protons of $\mathbf{2 e}$ with oxygen atoms of the substituted $p$-benzoquinone.

## Introduction

In the photoinduced electron transfer in bacterial photosynthetic reaction centres, quinone derivatives, which are bound to the protein by hydrogen bonding to the carbonyl oxygens, play an important role as the electron acceptor. ${ }^{1-4}$ Constructions of the artificial porphyrin-quinone assembly have been attained by considering noncovalent interactions based on the two- and four-point hydrogen bonding of meso substituted naphthols on the porphyrin ring, ${ }^{5-8}$ the redox coupling of hydroquinone attached to the porphyrin ring, ${ }^{9}$ and the amide hydrogen bonding of the macrocyclic tetraamide which fulfils the role of a scaffold by the incorporation of a metalloporphyrin coordination. ${ }^{10,11}$ More direct hydrogen bonding of the amide substituents attached to the porphyrin ring affords another promising strategy for the porphyrin-quinone assembly, ${ }^{12}$ since the acidity of the amide hydrogen can be controlled by varying the attached acyl group and, moreover, the multipoint hydrogen bonding can be constructed by the introduction of a functionalized acyl group. In this paper, we would like to demonstrate the $p$-benzoquinone recognition ability of 5,15-cis-bis(2-amidophenyl)-2,8,12,18-tetraethyl-3,7,13,17tetramethylporphyrins 2 and, in particular, to focus upon the effect of the introduced acyl group on the association constant for the porphyrin $-p$-benzoquinone complexation.

## Results and discussion

The recognising ability for $p$-benzoquinone (3a) was evaluated
with respect to perfluoroheptanecarboxamido-, heptanecarbox-amido-, trifluoroacetamido-, acetamido-, pentafluorobenz-amido-, and benzamidoporphyrins ( $\mathbf{2 a}, \mathbf{2 b}, \mathbf{2 c}, \mathbf{2 d}, \mathbf{2 e}$, and $\mathbf{2 f}$, respectively), together with the trans-isomer of $\mathbf{2 a}$ ( $\mathbf{2 a}$-trans) and 5,15-cis-bis(2-aminophenyl)-2,8,12,18-tetraethyl-3,7,13,17tetramethylporphyrin (1). Porphyrins $\mathbf{2 c}$ and $2 \mathbf{d}$ were prepared by the acylation of $\mathbf{1}$ with the corresponding anhydride in 78 and $71 \%$ yield, respectively. ${ }^{13}$ Porphyrins 2a, 2b, 2e, and $\mathbf{2 f}$ were obtained by the acylation of $\mathbf{1}$ with the corresponding acyl chloride in $73,80,63$, and $98 \%$ yield, respectively (Scheme 1). The trans-isomer ( $\mathbf{2 a}$-trans) was prepared from the trans-isomer of $\mathbf{1}$ in $80 \%$ yield.
Determination of the association constant for the porphyrin-3a complexation was first attempted by UV titration; however, it was found that the absorption change in the presence of varying amounts of $\mathbf{3 a}$ was too small for the titration. The Stern-Volmer plot for the fluorescence quenching of porphyrin with 3 a indicates a linear correlation, which must be based on intermolecular collision of photoexcited porphyrin and a quinone molecule. The reliable intracomplex quenching, which can make possible the Benesi-Hildebrand treatment, is not realised. The ${ }^{1} \mathrm{H}$ NMR technique is another plausible method for the titration. The ${ }^{1} \mathrm{H}$ NMR spectrum of a mixture of porphyrin 2a and 3a showed sharp and single resonances for downfield-shifted amide protons of 2a and for upfield-shifted protons of $\mathbf{3 a}$, which are consistent with the face-to-face structure 4. The association constant for the porphyrin-3a complexation was evaluated from the ${ }^{1} \mathrm{H}$ NMR titration for the change of the downfield-shifted amide protons of porphyrin, the con-

${ }^{a}$ The association constants were determined by ${ }^{1} \mathrm{H}$ NMR titration, the concentration of porphyrin being $2.5 \times 10^{-3} \mathrm{M}$.
centration of porphyrin being $2.5 \times 10^{-3} \mathrm{M}$ and that of 3 a being varied from 1 to 200 equimolar amount in $\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3^{-}}$ $\mathrm{CDCl}_{3}(10: 1) .{ }^{14}$ The results are collected in Table 1.

The appreciable association constant of $\mathbf{2 a}$, compared with that of 2a-trans, supports the two-point hydrogen bonding described in structure 4. The negligible association constant of porphyrin $\mathbf{1}$ indicates not only the weak hydrogen bonding of amino protons but also the weak $\pi-\pi$ stacking of the aminophenyl substituted porphyrin ring and of the aminophenyl ring itself with 3a. ${ }^{15}$ Porphyrin 2a is expected to show more rigid complexation than $\mathbf{2 b}$, since the amide protons of $\mathbf{2 a}$ are more acidic than those of $\mathbf{2 b}$ because of the strongly withdrawing fluorine group. However, a slight preference of 2b over 2a in association constants is in evidence, which indicates that the complexation is affected by both the acidity of the amide protons and the steric effect of the substituent, because the non-flexibility of the perfluoroalkyl group, other than its electron-withdrawing effect, is well known. ${ }^{16}$

Trifluoroacetamidoporphyrin 2c, the trifluoromethyl group of which is expected to be small enough for the complexation, was next evaluated; the association constant was attained and was found to be greater than that of acetamidoporphyrin 2d. It is remarkable that pentafluorobenzamidoporphyrin 2e recognises 3a effectively, its association constant being comparable to that of trifluoroacetamidoporphyrin $\mathbf{2 c}$, and this is in sharp contrast to the negligible association constant of benzamidoporphyrin $2 \mathbf{f}$.

The complexation equilibria of the selected porphyrins $\mathbf{2 c}$, $\mathbf{2 d}, \mathbf{2 e}$, and $\mathbf{2 f}$ with $p$-benzoquinone 3a were next followed by similar ${ }^{1} \mathrm{H}$ NMR titration at various temperatures. The obtained association constants are summarized in Table 2 and the satisfactorily linear van't Hoff plot, giving the relationship between the association constants and temperature, is described in Fig. 1. The thermodynamic parameters, which are evaluated by the van't Hoff equation, are also collected in Table 2. As was expected, the sufficiently negative free energy change of the complex with 2 c is mainly affected not by entropy change but by enthalpy change, which shows that the trifluoromethyl group is acting as a strongly electron-withdrawing group of comparable size to the methyl group in 2d. On the contrary, it is of interest that the small entropy change of the complex with $\mathbf{2 e}$ overcomes a slight decrease in enthalpy change, compared with 2d, and facilitates the formation of the complex. It is likely that the small entropy change is due to the mesomeric delocalization between the pentafluorophenyl group and the carbonyl group in both 2e and its complex with 3a, resulting in the restriction of the free rotation of the pentafluorophenyl group. It should be added that the small negative free energy change in the case

Fig. 1 van't Hoff plots for porphyrin- $p$-benzoquinone complexation in $\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3}-\mathrm{CDCl}_{3}(10: 1)$. O, 2e-3b $(r=0.9985)$; $\leqslant$ 2c-3a $(r=$ $0.9998)$; $\nabla$, 2e-3a $(r=9990)$; ■, 2d-3a $(r=0.9998)$; $\triangle$, 2e-3c $(r=$ $0.9947) ; \times, \mathbf{2 f}-\mathbf{3 a}(r=0.9936)$.
of $\mathbf{2 f}$ reflects the considerable decrease in the enthalpy change, rather than the entropy change, and this seems to be caused by the weakly electron-withdrawing property of the phenyl group in $2 f$.
The recognising ability for electron-rich tetramethyl $p$-benzoquinone ( $\mathbf{3 b}$ ) and electron-deficient tetrafluoro- $p$-benzoquinone (3c) was next evaluated using pentafluorobenzamidoporphyrin 2e. As shown in Table 2, the electron-releasing methyl group brings about an outstanding increase in association constants and conversely the electron-withdrawing fluorine atom leads to a decrease in the association constant, compared with that of 3a. This order $\mathbf{3 b}>\mathbf{3 a}>\mathbf{3 c}$ in association constants is primarily caused by enthalpy change. It is realised that the small enthalpy change in the case of $\mathbf{3 c}$ demonstrates the negligible contribution of the $\pi-\pi$ stacking between electron-donating porphyrin and electron-accepting tetrafluorobenzoquinone 3c. Hydrogen bonding of the amide protons of $2 \mathbf{e}$ with the oxygen atoms of $p$-benzoquinones seems to play a main role in the complexation and it is supported by the calculated net charge of the oxygen atoms of $p$-benzoquinones; that is, the order of net charge -0.54 for $\mathbf{3 b}>-0.52$ for $\mathbf{3 a}>-0.46$ for $\mathbf{3 c}$ is parallel to the decreasing association constants $2 \mathrm{e}-\mathbf{3 b}>\mathbf{2 e - 3 a}>2 \mathrm{e}-3 \mathrm{c} .{ }^{17}$

In conclusion, (2-trifluoroacetamido- and 2-pentafluorobenzamido)porphyrins 2c and 2e have significant recognising ability for $p$-benzoquinone 3a and it should be noted that their recognising ability is as good as or slightly superior to that of (2-hydroxy-1-naphthyl)porphyrin analogues, association constants of which are reported to be $K=5.5 \times 10 \mathrm{M}^{-1}$ in $\mathrm{CDCl}_{3}$ (based on ${ }^{1} \mathrm{H}$ NMR titration) and $1.4 \times 10^{2} \mathrm{M}^{-1}$ in benzene (based on UV-VIS titration) at 298 K . Moreover, 2e recognises electron-rich $p$-benzoquinone more effectively than electrondeficient $p$-benzoquinone, which is ascribed to the enthalpy change of the complex, caused by the hydrogen bonding of amide protons of 2 e with oxygen atoms of the substituted $p$-benzoquinone.

## Experimental

The IR spectra were recorded on a JASCO A-100 spectrometer and samples were run as potassium bromide pellets. UV-Visible spectra were recorded with a JASCO Ubest-50 spectrometer and measured in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The ${ }^{1} \mathrm{H}$ NMR spectra were recorded with a JEOL JNM-GX270 ( 270 MHz ) or -LA400 $(400 \mathrm{MHz})$ spectrometer using tetramethylsilane as an internal standard, the chemical shifts being given in $\delta / \mathrm{ppm}$ downfield. Samples were taken in $\mathrm{C}_{6} \mathrm{D}_{5} \mathrm{CD}_{3}-\mathrm{CDCl}_{3}(10: 1)$ unless otherwise noted. The elemental analyses were measured with a Perkin-Elmer 2400 II CHN Analyzer.

## 5,15-cis-Bis(2-perfluoroheptanecarboxamidophenyl)-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (2a)

Triethylamine ( $200 \mathrm{mg}, 1.98 \mathrm{mmol}$ ) was added dropwise to a solution of aminophenylporphyrin $\mathbf{1}(100 \mathrm{mg}, 0.15 \mathrm{mmol})$ and perfluorooctanoyl chloride ( $800 \mathrm{mg}, 1.85 \mathrm{mmol}$ ) in 10 mL of THF. After being stirred at room temperature for 1 h , the solution was evaporated to leave a residue which was dissolved in chloroform. The mixture was washed with water and brine, dried over magnesium sulfate, and evaporated. The resulting solid was chromatographed on silica gel (hexane-ethyl acetate, $5: 1)$ to give 160 mg ( $73 \%$ yield) of 2a. Further purification was carried out by recrystallization from hexane-chloroform: mp $191-193^{\circ} \mathrm{C}$; IR $3380(\mathrm{NH}), 1730(\mathrm{C}=\mathrm{O}), 1210$ and $1240 \mathrm{~cm}^{-1}$ (C-F); ${ }^{1} \mathrm{H}$ NMR $\delta-1.98(\mathrm{~s}, 2 \mathrm{H}), 1.70(\mathrm{t}, J=7.6 \mathrm{~Hz}, 12 \mathrm{H}), 2.48$ (s, 12 H$), 3.85(\mathrm{q}, J=7.6 \mathrm{~Hz}, 8 \mathrm{H}), 7.30(\mathrm{t}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}), 7.60$ $(\mathrm{m}, 4 \mathrm{H}), 8.0(\mathrm{~s}, 2 \mathrm{H}), 8.85(\mathrm{~d}, J=8.6 \mathrm{~Hz}, 2 \mathrm{H}), 10.30(\mathrm{~s}, 2 \mathrm{H}) ; \mathrm{UV}$ $\lambda_{\text {max }} \mathrm{nm}\left(\log \varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right) 626.5$ (3.05), 575 (3.34), 540 (3.37), 506.5 (3.72), 405.5 (4.79). Anal. Calcd. for $\mathrm{C}_{60} \mathrm{H}_{46} \mathrm{~N}_{6}-$ $\mathrm{F}_{30} \mathrm{O}_{2}: \mathrm{C}, 49.58 ; \mathrm{H}, 3.19 ; \mathrm{N}, 5.79$. Found: C, 49.29; H, 3.12; N, 5.98\%.

## 5,15-trans-Bis(2-perfluoroheptanecarboxamidophenyl)-2,8,12, 18-tetraethyl-3,7,13,17-tetramethylporphyrin (2a-trans)

In a similar manner to the above, acylation of 5,15-trans-bis(2-aminophenyl)-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin with perfluorooctanoyl chloride gave $80 \%$ yield of 2atrans: mp 239-241 ${ }^{\circ} \mathrm{C}$ (recrystallized from hexane-chloroform); IR 3375 (NH), 1730 (C=O), 1260, 1200, and $1140 \mathrm{~cm}^{-1}$ (C-F); ${ }^{1} \mathrm{H}$ NMR $\delta-2.0(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 1.70(\mathrm{t}, J=7.6 \mathrm{~Hz}, 12 \mathrm{H}), 2.50(\mathrm{~s}$, $12 \mathrm{H}), 3.85(\mathrm{q}, J=7.6 \mathrm{~Hz}, 8 \mathrm{H}), 7.30(\mathrm{t}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}), 7.60(\mathrm{~m}$, 4 H ), 8.00 (s, 2H ), 8.90 (d, $J=8.6 \mathrm{~Hz}, 2 \mathrm{H}$ ), $10.30(\mathrm{~s}, 2 \mathrm{H})$; UV $\lambda_{\text {max }} \mathrm{nm}\left(\log \varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right) 626.5$ (3.04), 575 (3.34), 539.5 (3.37), 506 (3.73), 405 (4.79). Anal. Calcd. for $\mathrm{C}_{60} \mathrm{H}_{46} \mathrm{~N}_{6} \mathrm{~F}_{30} \mathrm{O}_{2}$ : C, 49.58; H, 3.19; N, 5.79. Found: C, 49.57; H, 2.83; N, 5.56\%.

## 5,15-cis-Bis(2-heptanecarboxamidophenyl)-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (2b)

Similar acylation of $\mathbf{1}$ using octanoyl chloride afforded $80 \%$ yield of 2b: mp $258-261{ }^{\circ} \mathrm{C}$ (recrystallized from hexanechloroform); IR $3400(\mathrm{NH}), 1700 \mathrm{~cm}^{-1}$ (C=O); ${ }^{1} \mathrm{H}$ NMR $\delta-1.90(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 0.3-0.95(\mathrm{~m}, 30 \mathrm{H}), 1.70(\mathrm{t}, J=7.6 \mathrm{~Hz}, 12 \mathrm{H})$,
$2.65(\mathrm{~s}, 12 \mathrm{H}), 3.90(\mathrm{q}, J=7.6 \mathrm{~Hz}, 8 \mathrm{H}), 6.90(\mathrm{~s}, 2 \mathrm{H}), 7.25(\mathrm{t}$, $J=7.6 \mathrm{~Hz}, 2 \mathrm{H}), 7.60(\mathrm{~m}, 4 \mathrm{H}), 9.20(\mathrm{~d}, J=8.8 \mathrm{~Hz}, 2 \mathrm{H}), 10.27(\mathrm{~s}$, 2 H ); UV $\lambda_{\text {max }} \mathrm{nm}\left(\log \varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right) 626.5$ (3.18), 575 (3.48), 540.5 (3.52), 506.5 (3.86), 406 (4.94). Anal. Calcd. for $\mathrm{C}_{60} \mathrm{H}_{76} \mathrm{~N}_{6} \mathrm{O}_{2}: \mathrm{C}, 78.90 ; \mathrm{H}, 8.39 ; \mathrm{N}, 9.21$. Found: C, 78.80 ; H, 8.11; N, $8.95 \%$.

## 5,15-cis-Bis(2-trifluoroacetamidophenyl)-2,8,12,18-tetraethyl-3,7,13,17-tetramethylporphyrin (2c)

Similar acylation of $\mathbf{1}$ using trifluoroacetic anhydride afforded $78 \%$ yield of 2c: mp $335-336.5^{\circ} \mathrm{C}$ (dec.) (recrystallized from hexane-chloroform); IR $3375(\mathrm{NH}), 1735(\mathrm{C}=\mathrm{O}), 1150 \mathrm{~cm}^{-1}$ $\left(\mathrm{CF}_{3}\right) ;{ }^{1} \mathrm{H}$ NMR $\delta-1.90(\mathrm{br} \mathrm{s}, 2 \mathrm{H}), 1.67(\mathrm{t}, J=7.6 \mathrm{~Hz}, 12 \mathrm{H})$, $2.49(\mathrm{~s}, 12 \mathrm{H}), 3.82(\mathrm{~m}, 8 \mathrm{H}), 7.24(\mathrm{~m}, 2 \mathrm{H}), 7.51(\mathrm{dd}, J=7.6,1.5$ $\mathrm{Hz}, 2 \mathrm{H}), 7.56(\mathrm{~m}, 2 \mathrm{H}), 8.04(\mathrm{~s}, 2 \mathrm{H}), 8.87(\mathrm{dd}, J=8.5,1.0 \mathrm{~Hz}$, $2 \mathrm{H}), 10.28(\mathrm{~s}, 2 \mathrm{H})$; UV $\lambda_{\text {max }} \mathrm{nm}\left(\log \varepsilon / \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right) 626.5$ (3.47), 575 (3.79), 540.5 (3.82), 506.5 (4.18), 406 (5.26). Anal. Calcd. for $\mathrm{C}_{48} \mathrm{H}_{46} \mathrm{~N}_{6} \mathrm{~F}_{6} \mathrm{O}_{2}: \mathrm{C}, 67.58 ; \mathrm{H}, 5.44 ; \mathrm{N}, 9.86$. 14 The association constant is obtained from the slope and intercept of
the plot based on the following equation, $1 / \Delta \delta_{\text {obsd }}(N H)=\left\{1 / \Delta \delta_{\text {comp }^{-}}\right.$ $(\mathrm{NH})\}+(1 / K) \quad\left\{1 / \Delta \delta_{\text {comp }}(\mathrm{NH})\right\} \quad\left\{1 /[p \text {-benzoquinone }]_{\text {total }}\right\}$, where $\Delta \delta_{\text {obsd }}(\mathrm{NH})=\delta_{\text {obsd }}(\mathrm{NH})-\delta_{2}(\mathrm{NH}), \quad \Delta \delta_{\text {comp }}(\mathrm{NH})=\delta_{\text {comp }}(\mathrm{NH})-$ $\delta_{2}(\mathrm{NH})$, and $\delta_{2}(\mathrm{NH})$ is the chemical shift of the amide protons of the free porphyrin $2 .{ }^{5}$
