Received (in Cambridge, UK) 18th August 1999, Accepted 12th October 1999

The objective of the research was to study the effects of alkylidene bridges on the conformations and the conformational behaviour of overcrowded homomerous bistricyclic aromatic ethenes (1). The isopropylidenebridged bistricyclic ethene $\mathbf{2}$ and $\mathbf{3}$ were synthesized by a reductive "dimerization" of $\mathbf{7}$, using $\mathrm{TiCl}_{4}-\mathrm{Zn}$-pyridine-THF. The methylene-bridged bistricyclic ethenes $\mathbf{4} \mathbf{6}$ were synthesized by $\mathrm{LiAlH}_{4}-\mathrm{AlCl}_{3}-\mathrm{Et}_{2} \mathrm{O}$ reductions of the corresponding bianthrones. The structures of 2-6 were established by ${ }^{1} \mathrm{H}-$ and ${ }^{13} \mathrm{C}$-NMR spectroscopy and in the cases of $\mathbf{2}$ and $\mathbf{3}$, also by X-ray analysis. Compounds $\mathbf{2}$ and $\mathbf{3}$ adopted $C_{\mathrm{i}}$-anti-folded conformations with $53.0^{\circ}$ and $28.8^{\circ}$ folding dihedrals between pairs of benzene rings of tricyclic moieties. The central $\mathrm{C}_{9}=\mathrm{C}_{9}$, bond in $\mathbf{2}$ was essentially planar. A short $\mathrm{C}_{9} \cdots \mathrm{C}_{10}$ distance of $2.81 \AA$ in $\mathbf{2}$ indicated an intramolecular overcrowding effect in the highly folded bistricyclic ethene. Semiempirical PM3 and AM1 calculations of the anti-folded, syn-folded, twisted and orthogonally twisted conformations of $\mathbf{2}$ and $\mathbf{4}$ indicated that anti-folded $\mathbf{2}$ and $\mathbf{4}$ were the most stable conformations with folding dihedrals of $48.7^{\circ}$ and $45.0^{\circ}$, respectively at AM1. A DNMR spectroscopic study of $E$, $Z$-isomerizations and conformational inversions gave $\Delta G_{\mathrm{c}}^{\ddagger}(E \rightleftharpoons Z)=99.6 \mathrm{~kJ} \mathrm{~mol}^{-1}\left(\mathrm{CDBr}_{3}\right)$ and $\Delta G_{\mathrm{c}}^{\#}$ (inversion) $=$ $97.9 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (hexachlorobutadiene) in $\mathbf{5}$ and $\Delta G_{\mathrm{c}}^{\ddagger}{ }^{\ddagger}$ (inversion) $>108 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (benzophenone) in $\mathbf{3}$. These high energy barriers were interpreted in terms of less overcrowded fjord regions in the anti-folded ground-state conformations.

## Introduction

Bistricyclic aromatic enes (1) have served as attractive sub-

strates for the study of the conformations and dynamic stereochemistry of overcrowded ethenes. ${ }^{1-3}$ Several of these systems, e.g., bianthrone ( $\mathbf{1}, \mathrm{X}=\mathrm{Y}: \mathrm{C}=\mathrm{O}$ ) and dixanthylene ( $\mathbf{1}, \mathrm{X}=\mathrm{Y}: \mathrm{O}$ ), display thermochromic, photochromic and piezochromic properties. ${ }^{3}$ The bistricyclic enes are nonplanar due to the intramolecular overcrowding in their fjord regions. ${ }^{3}$ The nonplanarity introduces the notion of chirality to the arena of these interesting compounds. ${ }^{4}$ Two principal modes of out-ofplane deviation were considered: twisting around the central carbon-carbon double bond and out-of-plane bending. ${ }^{5}$ In 1, the bending is realized by folding of the tricyclic moieties at both ends of the central ene about the $\mathrm{C}_{9} \cdots \mathrm{X}$ and $\mathrm{C}_{9}, \cdots \mathrm{Y}$ axes, resulting in boat conformations of the central rings. In addition, the atoms $\mathrm{C}_{9}$ and $\mathrm{C}_{9}$, may be pyramidalized. Four pure conformations of $\mathbf{1}$ were considered: the twisted ( $\mathbf{t}$ ), the anti-folded (a), the syn-folded (s) and the orthogonally twisted ( $\mathbf{t}_{\perp}$ ) conformations (Fig. 1). ${ }^{3}$ Homomerous bistricyclic enes (1,

[^0]
twisted

orthogonal

Fig. 1 Schematic projection along $\mathrm{C}_{9}=\mathrm{C}_{9}$, of various types of conformations of bistricyclic enes (lines represent the peripheral benzene rings of the tricyclic moieties).
$\mathrm{X}=\mathrm{Y}$ ) with five-membered and six-membered central rings adopt twisted conformations ( $\mathbf{t}$ ) and anti-folded (a) conformations, respectively. ${ }^{3}$

Bistricyclic enes may undergo the following fundamental dynamic processes: ${ }^{3}$

1. $E, Z$-isomerization (e.g., $\mathbf{t}_{E} \rightleftharpoons \mathbf{t}_{Z}, \mathbf{a}_{E} \rightleftharpoons \mathbf{a}_{Z}$ ),
2. Conformational inversion, e.g., inversion of the helicity in the twisted $\mathbf{1}\left(\mathbf{t}_{P} \rightleftharpoons \mathbf{t}_{M}\right)$ or inversion of the boat conformation in the central rings of folded $\mathbf{1}$,
3. syn, anti-isomerization $(\mathbf{a} \rightleftharpoons \mathbf{s})$, anti, twisted-isomerization $(\mathbf{a} \rightleftharpoons \mathbf{t})$ and $\operatorname{syn}$, twisted-isomerization $(\mathbf{s} \rightleftharpoons \mathbf{t})$.
4. Enantiomerization and racemization may also be considered in these processes.
The dynamic stereochemistry of bistricyclic enes $\mathbf{1}$ with central six-membered rings have been studied by Agranat et al., and by Feringa et al., using dynamic NMR (DNMR) and equilibration techniques, when one of the conformational isomers is available in a pure form. ${ }^{3-9}$ The DNMR studies revealed low barriers for thermal $E, Z$-isomerization $\left(\Delta G_{\mathrm{c}}^{\ddagger}=75-115 \mathrm{~kJ}\right.$ $\mathrm{mol}^{-1}$ )..$^{3,6-10}$ The range of free energies of activation for thermal conformational inversion of bistricyclic enes with central sixmembered rings was found to be similar. These remarkably low energy barriers were interpreted predominantly in terms of ground state destabilization due to steric strain and overcrowding. ${ }^{3}$ It has been shown that the barriers depend on the bridges

X and Y , on the $\mathrm{C}-\mathrm{X}$ and $\mathrm{C}-\mathrm{Y}$ bond lengths, and on the $\mathrm{C}_{4 \mathrm{a}}{ }^{-}$ $\mathrm{C}_{10 \mathrm{a}}$ distances. ${ }^{6}$

The present article describes the syntheses, molecular and crystal structures, semiempirical calculations and DNMR study of homomerous bistricyclic enes with methylene and isopropylidene bridges $\left(\mathbf{1}, \mathrm{X}=\mathrm{Y}: \mathrm{CH}_{2}\right.$ and $\left.\mathbf{1}, \mathrm{X}=\mathrm{Y}: \mathrm{CMe}_{2}\right)$. In these systems, the $\mathrm{C}_{\mathrm{sp}^{2}-} \mathrm{C}_{\text {sp }^{3}}$ bonds at the bridges $\left(\mathrm{C}_{4 \mathrm{a}}-\mathrm{C}_{10}\right.$ and $\mathrm{C}_{10}-\mathrm{C}_{10 \mathrm{a}}$ ) are expected to be longer than the corresponding $\mathrm{C}_{4 \mathrm{a}}-\mathrm{X}$ and $\mathrm{C}_{4 \mathrm{a}}-\mathrm{Y}$ in dixanthylene, $N, N^{\prime}$-dimethylbiacridan and bianthrone. ${ }^{3}$ The alkylidene-bridged $\mathbf{1}$ are thus expected to possess a higher degree of folding and to be less overcrowded in the fjord regions. Furthermore, the methylene and isopropylidene bridges contain axial and equatorial hydrogen atoms and methyl groups in the boat-shaped central six-membered rings, which in principle allow a determination of the inversion barriers of the parent bistricyclic enes. Heteromerous bistricyclic enes with one $\mathrm{CMe}_{2}$ bridge have previously been studied. ${ }^{11}$

## Synthesis

The following compounds were synthesized: 10-[10,10-dimethyl-9 $(10 H)$-anthracenylidene]-9,10-dihydro-9,9-dimethylanthracene (2), 10-[10,10-dimethyl- $9(10 H)$-anthracenyl]-9,10-

E-6

$Z-6$
dihydro-9,9-dimethylanthracene (3), 9-[9(10H)-anthracenyl-idene]-9,10-dihydroanthracene (4), 9 -[2-methyl- $9(10 \mathrm{H})$ -anthracenylidene]-9,10-dihydro-2-methylanthracene (5) and 5-[3-methyl-5(12H)-naphthacenylidene]-5,12-dihydro-3-methylnaphthacene (6). The synthesis of $\mathbf{2}$ was accomplished by a low-valent titanium-induced reductive "dimerization" of $10,10-$ dimethylanthracen- $9(10 \mathrm{H})$-one (7) using the MukaiyamaLenoir procedure ${ }^{12-14}$ of the McMurry reaction ${ }^{15}\left(\mathrm{TiCl}_{4}-\mathrm{Zn}-\right.$ pyridine-THF) (Scheme 1). The reaction afforded a $1: 3$ mixture of $\mathbf{2}$ and $\mathbf{3}$ in $66 \%$ yield. The products were separated and purified by recrystallizations. Hydrocarbon 2 has been prepared by a reductive "dimerization" of 7, using zinc in $\mathrm{AcOH}-\mathrm{HCl} .{ }^{16}$ Hydrocarbon $\mathbf{3}$ has been prepared by hydrogenation of $\mathbf{2}$, using sodium in pentan-1-ol. ${ }^{16}$

Compounds $\mathbf{4 - 6}$ were synthesized by $\mathrm{LiAlH}_{4}-\mathrm{AlCl}_{3}$ reduction of bianthrone, $2,2^{\prime}$-dimethylbianthrone and 12-[3-methyl-12-oxo- $5(12 \mathrm{H})$-naphthacenylidene]-2-methylnaphthacen$5(12 \mathrm{H})$-one, respectively. The synthesis of $\mathbf{4}$ by a $\mathrm{LiAlH}_{4}$ reduction of bianthrone ${ }^{17}$ and by a reductive "dimerization" of anthrone using aluminium in $\mathrm{CH}_{3} \mathrm{CN}$ under the irradiation of ultrasonic wave ${ }^{18}$ has been reported. Compounds 5 and $\mathbf{6}$ were obtained as mixtures of $E$ - and $Z$-diastereomers. The synthesis

Scheme 2
of $(E)-5$ and $(Z)-5$ is depicted in Scheme 2. The structures of 2-6 were established by NMR spectroscopy and elemental analysis. It is possible to distinguish qualitatively among the twisted, syn-folded and anti-folded conformations of homomerous bistricyclic enes ( $\mathbf{1}, \mathrm{X}=\mathrm{Y}$ ) in solution, using ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectroscopy. In the cases of $\mathbf{2}$ and $\mathbf{4}$, the fjord region protons appear at 7.010 and 6.984 ppm , respectively, indicating that these hydrocarbons adopt anti-folded conformations in solution. ${ }^{3,8}$ A similar picture appears in 5 and $\mathbf{6}$. In the case of 4, complete assignments were made through two-dimensional correlation spectroscopy (COSY, HSOC, HMBC, NOESY). In the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of 4 , the methylene protons appear as an AB system at 4.240 and 3.865 ppm . The doublet at 4.240 ppm representing one of the protons of each methylene group was broad, while the second doublet at 3.865 ppm representing the other proton of each methylene group was sharp. In the aromatic region, the double doublet at 7.365 ppm representing $\mathrm{H}_{4}, \mathrm{H}_{5}, \mathrm{H}_{4}, \mathrm{H}_{5^{\prime}}$, was also broad. A COSY experiment indicated an allylic coupling between the 7.365 ppm doublet and the 4.240 ppm doublet. A NOESY experiment indicated through space interactions between the 7.365 ppm doublet and the 3.865 ppm doublet. On the basis of these experiments, it is concluded

Fig. 2 An ORTEP drawing of 2 derived from the X-ray crystal structure.
that the 3.865 ppm doublet is due to the equatorial $\mathrm{H}_{10 \text { eq }}$ while the 4.240 ppm doublet is due to the axial $\mathrm{H}_{10 a x}$.

## Molecular and crystal structures §

Compounds 2 and 3 crystallized in the space group $\mathrm{P}_{1} / c .^{19}$ Fig. 2 gives an ORTEP diagram of one molecule of $\mathbf{2}$ as determined by X-ray analysis. Table 1 gives the conformations and selected geometrical parameters of 2-4 derived from the crystal structures and from semiempirical calculations (vide infra).
The molecular and crystal structures of $\mathbf{2}$ show that the molecule adopts a $C_{\mathrm{i}}$-anti-folded conformation (a-2). The folding dihedral angle (between the least-squares-planes of the two benzene rings of each tricyclic moiety) of $\mathbf{2}$ is $53.0^{\circ}$. For comparison, the degree of folding of a metalo-based $\left(\mathrm{PdCl}_{2}\right.$ bridge) bistricyclic ene with the 9,9-dimethyl-9,10-dihydroanthracenylidene moiety is $48.8^{\circ} .^{11}$ The degree of overcrowding in the fjord regions of $\mathbf{2}$, as reflected in the intramolecular distances $\mathrm{C}_{1} \cdots \mathrm{C}_{1^{\prime}}, \mathrm{C}_{1} \cdots \mathrm{H}_{1^{\prime}}$, and $\mathrm{H}_{1} \cdots \mathrm{H}_{1^{\prime}}$, is hardly significant: 3.13, 2.97 and $3.11 \AA$, respectively. For comparison, the van der Waals radii of carbon and hydrogen are 1.71 and $1.15 \AA$, resulting in van der Waals $\mathrm{C} \cdots \mathrm{C}, \mathrm{C} \cdots \mathrm{H}$ and $\mathrm{H} \cdots \mathrm{H}$ contact distances of $3.42 \AA, 2.86$ and $2.30 \AA$, respectively. ${ }^{20}$ The above $\mathrm{C}_{1} \cdots \mathrm{C}_{1^{\prime}}$ distance in 2 reflects only an $8 \%$ penetration, while the above $\mathrm{C}_{1} \cdots \mathrm{H}_{1^{\prime}}$ and $\mathrm{H}_{1} \cdots \mathrm{H}_{1^{\prime}}$ distances do not indicate any penetration. On the other hand, the transannular $\mathrm{C}_{9} \cdots \mathrm{C}_{10}$ distance, $2.81 \AA$ is considerably shorter than the $\mathrm{C} \cdots \mathrm{C}$, van der Waals contact distance, reflecting an $18 \%$ penetration. These short distances indicate an additional effect of intramolecular overcrowding in highly folded bistricyclic enes.

In the previously reported structures of anti-folded homomerous bistricyclic enes, pyramidal $\mathrm{C}_{9}=\mathrm{C}_{9}$, carbon atoms have been noted. However, the central carbon-carbon double bond in 2 is essentially planar, with negligible values of the pyramidalization angles $\chi_{9}$ and $\chi_{9}{ }^{3}$ and a pure twist of zero. ${ }^{3}$ The $\mathrm{C}_{9}=\mathrm{C}_{9}$, bond length is $1.347 \AA$. The relatively long $\mathrm{C}_{4 \mathrm{a}}-\mathrm{C}_{10}$ bonds at the bridges, $1.534 / 1.531 \AA$, probably enhance the degree of folding. Overcrowding is also evident in the short contact distances between a methyl hydrogen and the corresponding peri-hydrogens $\left(\mathrm{H}_{4}, \mathrm{H}_{5}\right): 2.16 \AA$.

Fig. 3 An ORTEP drawing of 3 derived from the X-ray crystal structure.

Fig. 3 gives an ORTEP diagram of $\mathbf{3}$ as determined by X-ray analysis. The molecular and crystal structure of $\mathbf{3}$ show that the molecule adopts a $\mathrm{C}_{\mathrm{i}}$-anti-folded conformation. The folding dihedral angle (A-B, C-D) is $28.8^{\circ}$. The length of the central $\mathrm{C}_{9}-\mathrm{C}_{9}$ is $1.587 \AA$. There is a certain degree of overcrowding: the $\mathrm{C}_{1} \cdots \mathrm{C}_{1^{\prime}}$ and $\mathrm{C}_{9} \cdots \mathrm{C}_{10}$ distances are 3.07 and $2.97 \AA$, respectively. The short $\mathrm{H}_{4} \cdots \mathrm{H}_{3} \mathrm{C}$ distance, $2.04 \AA$ should also be noted.

## Semiempirical calculations

Recently, a systematic theoretical survey of overcrowded homomerous and heteromerous bistricyclic enes $\mathbf{1}$ has been carried out, using MOPAC 6.00 and the semiempirical method PM3. ${ }^{3}$ The methylene- and isopropylidene-bridged bistricyclic enes $\mathbf{4}$ and $\mathbf{2}$ have been included, inter alia, in the modelling. ${ }^{3}$ The present article reports the results of the PM3 ${ }^{21}$ and AM1 ${ }^{22}$ calculations of $\mathbf{4}$ and 2, using MOPAC $93 .{ }^{23}$ Comparisons of AM1 with PM3 have been commented on. ${ }^{24,25}$ The following conformations of 2 and $\mathbf{4}$ have been considered: $C_{2 \mathrm{~h}}$-anti-folded-2 (a-2), $C_{2 \mathrm{v}}$-syn-folded-2 ( $\mathbf{s}-2$ ), $\mathrm{C}_{2}$-syn-folded-2 ( $C_{2}$-s-2), $D_{2}$-twisted-2 (t-2), $\quad C_{2}$-twisted-2 $\left(C_{2}\right.$-t-2), $\quad D_{2 \mathrm{~d}}$-orthogonally twisted $-2\left(\mathbf{t}_{\perp}-\mathbf{2}\right)$, and the corresponding conformations of $\mathbf{4}, \mathrm{a}-\mathbf{4}$, $\mathbf{s - 4}, \mathbf{t}-4$ and $\mathbf{t}_{-}-\mathbf{4}$. The various conformations have been fully optimized (Keywords: EF SYMMETRY PRECISE GNORM $=0.1$ LET DDMIN $=0.0$; for orthogonal conformations BIRADICAL was added) and their vibrational frequencies calculated (Keywords: FORCE PRECISE SYMMETRY; for orthogonal conformations BIRADICAL was added). The following conformations were found to be bona fide minima (positive vibrational frequencies): $C_{2 \mathrm{~h}}-\mathbf{a}-\mathbf{2}, C_{2}-\mathbf{s}-\mathbf{2}, C_{2}-\mathbf{t} \mathbf{- 2}, C_{2 \mathrm{~h}}-\mathbf{a}-$ 4, $C_{2 \mathrm{v}}-\mathrm{s}-\mathbf{4}$ at PM3, $C_{2 \mathrm{~h}}-\mathrm{a}-2, C_{2}-\mathrm{s} \mathbf{2}, D_{2}-\mathbf{t - 2}, C_{2 \mathrm{~h}}-\mathrm{a}-4, C_{2 \mathrm{v}}-\mathrm{s}-4$ at AM1. The following conformations were found to be transition states (one imaginary frequency): $C_{2 \mathrm{v}}-\mathrm{s}-\mathbf{2}, \mathrm{D}_{2}-\mathrm{t}-4$ and $D_{2 \mathrm{~d}}-\mathrm{t}_{-}-4$ at PM3, $D_{2 \mathrm{~d}} \mathrm{t}_{\mathrm{d}}-\mathbf{2}, D_{2}-\mathrm{t}-4$ and $D_{2 \mathrm{~d}} \mathrm{t}_{\mathbf{-}}-4$ at AM1. On the other hand, $D_{2}-\mathrm{t}-2$ at PM3 and $C_{2 v}$-s-2 at AM1 were found to be second order saddle points. Surprisingly, $D_{2 \mathrm{~d}} \mathbf{t}_{\mathrm{l}}-\mathbf{2}$ at PM3 was found to be a third order saddle point.

The semiempirical enthalpies of formation $\left(\Delta H_{\mathrm{f}}{ }^{\circ}\right)$ of the conformations of $\mathbf{2}$ and $\mathbf{4}$, the conformational energies ( $\Delta \Delta H_{\mathrm{f}}^{\circ}$ ) of $\mathbf{2}$ and $\mathbf{4}$ (relative to the respective anti-folded global minimum conformation) and selected geometrical parameters of the conformations of $\mathbf{2}$ and $\mathbf{4}$ derived from the PM3 and AM1 calculations are included in Table 1, together with the corresponding geometrical parameters derived from the crystal structures of $\mathbf{2}$ and 3. The 3D structures of the AM1 optimized s-2 and a-4 are given in Fig. 4 and Fig. 5. The most stable conformations of 2 and $\mathbf{4}$ are the anti-folded conformations a-2 and a-4. Their fold-

ing dihedrals are $48.7^{\circ}$ and $45.0^{\circ}$ at AM1, as compared with $53.0^{\circ}$ in the crystal structures of 2. In a-2, the $\mathrm{C}_{4 \mathrm{a}}-\mathrm{C}_{10}$ bond at the bridge is elongated, $1.517 \AA$ (PM3) and 1.512 (AM1) as compared with a-4, $1.496 \AA$ (PM3) and $1.491 \AA$ (AM1).

In a-2, severe methyl, peri-H interactions are noted: the $\mathrm{CH}_{3} \cdots \mathrm{H}_{4}$ contact distance is $1.87 \AA(\mathrm{PM} 3)$ and $2.03 \AA$ (AM1). The short $\mathrm{CH}_{3} \cdots \mathrm{C}_{9}$ contact distance in a-2 should also be noted: $2.76 \AA$ (PM3) and $2.57 \AA$ (AM1). These values are only slightly shorter than the van der Waals hydrogen... carbon contact distance $(2.86 \AA) .{ }^{20}$ In $\mathbf{a}-4$, the $\mathrm{C}_{9} \cdots \mathrm{C}_{10}$ dis-
tance, $2.84 \AA$ (PM3) and $2.82 \AA$ (AM1) reflects considerable penetration of the van der Waals carbon $\cdots$ carbon contact distance, $3.42 \AA,{ }^{20} 17 \%$ (PM3) and 18\% (AM1). The anti-folded conformations are only slightly pyramidalized. However, both syn-folded conformations are markedly pyramidalized at $\mathrm{C}_{9}$ : $10.6^{\circ}$ (PM3) and $9.5^{\circ}$ (AM1) in $\mathrm{C}_{2 \mathrm{~V}}$-s-2 and $13.0^{\circ}$ (PM3) and $14.9^{\circ}$ (AM1) in s-4. The conformational energies of the synfolded conformation are 14.0 (PM3) and $39.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (AM1) in $C_{2}-\mathbf{s}-\mathbf{2}$ and 10.6 (PM3) and $29.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (AM1) in s-4. DFT ab initio calculations at B3LYP/6-31G*//HF/6-31G* on the

related $10,10^{\prime}$-dimethylene derivative of 4 indicated that the $s y n$-folded conformation is less stable than the anti-folded conformation by $39.1 \mathrm{~kJ} \mathrm{~mol}^{-1}{ }^{26}$ The syn-folded conformations show also short $H_{1} \cdots H_{1^{\prime}}$ contact distances at the fjord regions ( $1.72 \AA$ (PM3) and $2.04 \AA$ (AM1) in $C_{2}-\mathrm{s}-2$ and $1.74 \AA$ (PM3) and $1.94 \AA$ (AM1) in s-4). In $C_{2}$-s-2, very short $\mathrm{CH}_{3} \cdots \mathrm{H}_{3} \mathrm{C}$ distances between the bridges are noted: $1.67 \AA$ (PM3) and 2.07 $\AA$ (AM1). The conformational energies of the twisted conformations $\mathbf{t - 2}$ and $\mathbf{t - 4}$ are practically identical, $63 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (AM1). The $\mathbf{a}-\mathbf{4} \rightarrow \mathbf{s}-\mathbf{4}$ photoisomerization and a CFF- $\pi$ electron-CI calculation of s-4 have been reported. ${ }^{27,28}$

## DNMR Spectroscopy

The synthesis of $\mathbf{5}$ and $\mathbf{6}$ allowed a DNMR spectroscopic study of the conformational inversions and $E, Z$-isomerizations of these methylene-bridged bistricyclic enes. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum of $\mathbf{5}$ included two methyl singlets, indicating the presence of the $E$ - and $Z$-diastereomers. In an anti-folded conformation of $\mathbf{5}$, the symmetries of the $E$ - and $Z$-diastereomers are $C_{\mathrm{i}}$ and $C_{2}$ respectively; causing both methyl substituents in each diastereomer to be isochronous. The thermal $E, Z$-isomeriz-
ation was studied by monitoring the coalescence of the two methyl signals representing the $E$ - and the $Z$-diastereomers, respectively. The conformational inversion of 5 and $\mathbf{6}$ was studied by monitoring the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ coalescence of the AB system representing the diastereotopic axial and equatorial hydrogens of the $\mathrm{CH}_{2}$ bridges. It should be noted that in $\mathbf{5}$ and $\mathbf{6}$, there was not any difference in the chemical shifts of the hydrogens of the $\mathrm{CH}_{2}$ bridges between the $E$ - and the $Z$-diastereomers. The results of the DNMR study are summarized in Table 2. In the case of $\mathbf{5}, \Delta G_{\mathrm{c}}^{\ddagger}(E \rightleftharpoons Z)=99.6 \mathrm{~kJ} \mathrm{~mol}^{-1}\left(\right.$ in $\left.^{\mathrm{CDBr}}{ }_{3}\right)$ and $\Delta G_{\mathrm{c}}^{\ddagger}$ (inversion) $=97.9 \mathrm{~kJ} \mathrm{~mol}^{-1}$ (in hexachlorobutadiene). In 6, the corresponding $\Delta G_{\mathrm{c}}^{\ddagger}$ values were 100.4 and 96.7 kJ $\mathrm{mol}^{-1}$ (in 1-bromonaphthalene). In the isopropylidene-bridged 2, the ${ }^{1} \mathrm{H}-\mathrm{NMR}$ and ${ }^{13} \mathrm{C}$-NMR spectra led in each case to two separated singlets representing the axial and equatorial methyl groups. Upon a conformational inversion of 2, a $\mathrm{Me}_{a x} \rightleftharpoons \mathrm{Me}_{e q}$ interconversion would be expected. A DNMR experiment in naphthalene ( $\Delta v=35 \mathrm{~Hz}$ ) up to $207^{\circ} \mathrm{C}$ did not show any significant broadening of the two ${ }^{1} \mathrm{H}$ NMR methyl singlets, indicating that $\Delta G_{\mathrm{c}}^{\ddagger}>92 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Likewise, in benzophenone ( $\Delta v=3$ Hz ) at $190^{\circ} \mathrm{C}$, the two methyl ${ }^{1} \mathrm{H}$-NMR singlets could still be resolved indicating that $\Delta G_{\mathrm{c}}^{\ddagger}>108 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Feringa et al. have reported on the conformational inversion of a few cases of heteromerous bistricyclic enes with isopropylidene bridges. ${ }^{6}$ As in the case of 2, a DNMR study of metalo-bridged bistricyclic enes with $\mathrm{CMe}_{2}$ and $\mathrm{ZnCl}_{2}$ bridges and with $\mathrm{CMe}_{2}$ and $\mathrm{PdCl}_{2}$ bridges did not result in a coalescence of the methyl signals even at $200^{\circ} \mathrm{C}$ (in nitrobenzene- $\mathrm{d}_{5}$ ). ${ }^{11}$ The authors suggested that in these cases the results indicated considerable steric hindrance for the isomerization process inverting the folded conformations, and that metal binding results in folded structures completely inert towards interconversions. ${ }^{11}$ In the case of 9 -[10,10-dimethyl-9(10H)-anthracenylidene]-2-methyl-9 H thioxanthene in which the bridges are $\mathrm{CMe}_{2}$ and S , the racemization barrier $\Delta G_{\mathrm{c}}^{\ddagger}=105 \pm 1 \mathrm{~kJ} \mathrm{~mol}^{-1} .{ }^{6}$

Table 3 gives the free energies of activation for thermal $E, Z$ isomerizations and for thermal conformational inversions of various homomerous bistricyclic enes. The most remarkable result of the present DNMR studies is the relatively high and essentially identical values of the free energies of activation for the $E, Z$-isomerization and for the conformational inversion. These results are consistent with the mechanisms of the conformational processes of anti-folded bistricyclic enes depicted in Fig. 6 and 7. ${ }^{3}$ These mechanisms involve a common "edge passage" highest transition state. The higher energy barriers observed in the cases of the methylene-bridged and isopropyl-idene-bridged bistricyclic enes (e.g., $\mathbf{5}$ and $\mathbf{2}$ ) as compared with dixanthylenes ${ }^{8}$ and bianthrones ${ }^{9}$ are primarily due to the less overcrowded fjord regions in the anti-folded ground states of these systems. The longer $\mathrm{C}-\mathrm{X}$ bonds in $\mathbf{2 , 5}$ and $\mathbf{6}$ and the longer $\mathrm{C}_{4 \mathrm{a}} \cdots \mathrm{C}_{10 \mathrm{a}}$ bridge distance allow a higher degree of folding and thus a reduced overcrowding in the fjord regions. ${ }^{6}$ Such an effect is more pronounced in the case of the isopropylidenebridged 2 as compared with the methylene-bridged 4. The significantly higher barrier for the conformational inversion of $\mathbf{2}$ versus $\mathbf{5}\left(\Delta \Delta G_{\mathrm{c}}^{\ddagger}>8 \mathrm{~kJ} \mathrm{~mol}^{-1} \mathrm{e}\right)$ may also be ascribed to unfavorable steric interactions between one of the methyl groups of 2 and the fjord regions at the opposing ring (e.g., $\mathrm{CH}_{3} \cdots \mathrm{H}_{1^{\prime}}$ ) in the transition state, during the "edge passage".

## Experimental

Melting points are uncorrected. All NMR spectra were recorded with a Bruker DRX 400 spectrometer, unless otherwise stated. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 400.1 MHz using $\mathrm{CDCl}_{3}$ as solvent and as internal standard $\left(\delta\left(\mathrm{CHCl}_{3}\right)=\right.$ $7.26 \mathrm{ppm}) .{ }^{13} \mathrm{C}$ NMR spectra were recorded at 100.6 MHz using $\mathrm{CDCl}_{3}$ as solvent and as internal standard $\left(\delta\left(\mathrm{CHCl}_{3}\right)=77.01\right.$ $\mathrm{ppm})$. The barriers were determined by DNMR spectroscopy, substituting the coalescence temperature $T_{\mathrm{c}}$ and the extrapolated chemical shift difference $\Delta v_{\mathrm{c}}$ at $T_{\mathrm{c}}$ in the following equation for the Eyring Equation $\Delta G_{\mathrm{c}}^{\ddagger}=4.47 T_{\mathrm{c}}[9.97-\log$ $\left.\left(T_{\mathrm{c}} / \Delta v_{\mathrm{c}}\right)\right]$.

10-[10,10-Dimethyl-9(10H)-anthracenylidene]-9,10-dihydro-9,9dimethylanthracene (2) and 10-[10,10-dimethyl-9(10H)-anthra-cenyl]-9,10-dihydro-9,9-dimethylanthracene (3) ${ }^{29}$

The reaction was carried out under an argon atmosphere in a 500 mL three-necked round-bottomed flask equipped with a reflux condenser (protected from moisture), a dropping funnel, and a magnetic stirrer. Freshly distilled dry THF ( 200 mL distilled over sodium diphenyl ketyl) was added to the flask and cooled to $-5^{\circ} \mathrm{C}$. Dropwise slow injection of $\mathrm{TiCl}_{4}(1.85$ $\mathrm{mL}, 16.9 \mathrm{mmol}$ ) using a plastic syringe with continuous stirring gave a yellow complex, which was treated with Zn dust $(2.26 \mathrm{~g}, 35.5 \mathrm{mmol})$. The temperature was gradually raised to rt and kept for another 1 h to give a greenish suspension. The mixture was then refluxed for 5 h to complete the reduction,
giving a green-black suspension. After cooling to $0^{\circ} \mathrm{C}$, the mixture was treated with pyridine $(2 \mathrm{~mL})$, followed by dropwise addition over 3.5 h of a solution of ketone $7(3.50 \mathrm{~g}, 15.5$ $\mathrm{mmol})^{22}$ in dry THF ( 100 mL ). The resulting mixture was refluxed for 48 h . The disappearance of the starting material was monitored by TLC. After being cooled to room temperature, the mixture was added to dichloromethane ( 300 mL ), stirred vigorously and treated with aqueous $\mathrm{HCl}(0.1 \mathrm{M})$ to give two layers. The organic layer was separated, and the aqueous layer was extracted with dichloromethane. The organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$, and the solvents were removed in vacuum. The crude products ( 3.0 g ) were dissolved in dichloromethane and chromatographed on a silica column, using a hexane-diethyl ether gradient (up to $20 \%$ diethyl ether) as eluent. The chromatography afforded $2.1 \mathrm{~g}(65.6 \%$ yield) of the fluorescent yellow products. The ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectrum (vide infra) indicated a $1: 3$ mixture of 2 and 3. Recrystallization from benzene gave single crystals of 2 ( $1: 1$ complex with benzene), $\operatorname{mp~} 325^{\circ} \mathrm{C}$, suitable for X-ray analysis (lit., ${ }^{16}$ $\operatorname{mp} 312-313{ }^{\circ} \mathrm{C}$ ).

Crystal data. Compound 3: Formula $\mathrm{C}_{32} \mathrm{H}_{30}, M=414.59$, monoclinic, $a=12.139$ (4), $b=8.260$ (3), $c=11.816$ (3) $\AA$, $\beta=90.97$ (4) ${ }^{\circ}, V=1184.6$ (7) $\AA^{3}$, rt, space group $P 2_{1} / c$ (no.14), $Z=2, \mu(\mathrm{Mo}-\mathrm{K} \alpha)=0.33 \mathrm{~cm}^{-1}, 2269$ unique reflections of which 1553 were observed $\left(I>2 \sigma_{\mathrm{I}}\right), R=0.055, R_{\mathrm{w}}=0.068$.

## 9-[2-Methyl-9(10H)-anthracenylidene]-9,10-dihydro-2-methylanthracene (5)

The reaction was carried out in an argon atmosphere in a round-bottomed flask equipped with a reflux condenser (protected from moisture) and a magnetic stirrer. Dry diethyl ether $(30 \mathrm{ml})$ was added to the flask followed by anhydrous $\mathrm{AlCl}_{3}(3.6$ $\mathrm{g}, 27 \mathrm{mmol})$ in small portions and then by $\mathrm{LiAlH}_{4}(0.6 \mathrm{~g}, 15.8$ mmol ) in small portions. The mixture was stirred for 30 min at rt, dry benzene ( 50 ml ) was added followed by $2,2^{\prime}$-dimethylbianthrone (8) ${ }^{9}(0.25 \mathrm{~g}, 0.6 \mathrm{mmol})$ in small portions. The mixture was then refluxed at $80^{\circ} \mathrm{C}$ for 3 h . The excess $\mathrm{LiAlH}_{4}$ was decomposed by adding dropwise ethyl acetate and the mixture treated by water, followed by dilute aqueous HCl . The organic layer was separated and the aqueous layer extracted with dichloromethane. The combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$, and the solvents were removed in vacuum. The crude product was purified by preparative chromatography on a PLC silica plate, using benzene as eluent ( $R_{\mathrm{f}}=0.9$ ). Recrystallization from benzene-petrol ether $\left(40-60^{\circ} \mathrm{C}\right)$ gave $\mathbf{5}$ as a colorless powder, $\mathrm{mp} 265-272^{\circ} \mathrm{C}$, in $65 \%$ yield. The $E: Z$ ratio was $55: 45$ (or vice versa).

Anal. Calcd for $\mathrm{C}_{30} \mathrm{H}_{24}$ : C, 93.70; H, 6.30. 5-[3-Methyl-5(12H)-naphthacenylidene]-5,12-dihydro-3methylnaphthacene (6)
Hydrocarbon 6 was prepared by a $\mathrm{LiAlH}_{4}-\mathrm{AlCl}_{3}$ reduction of 2-methyl-12-[3-methyl-12-oxo-5(12H)-naphthacenylidene]-naphthacen- $5(12 H)$-one, ${ }^{9}$ analogously to 4 . The product was purified on a silica PLC plate, using dichloromethane-petrol ether $\left(40-60^{\circ} \mathrm{C}\right) 1: 1$ as eluent ( $R_{\mathrm{f}}=0.7$ ). Recrystallization from benzene-petrol ether $\left(40-60^{\circ} \mathrm{C}\right)$ gave $\mathbf{6}$ as a pale yellowish powder, $\mathrm{mp}>300^{\circ} \mathrm{C}$ (slow decomposition during heating to give a brown-red color). The yield was $72 \%$. The $E: Z$ ratio was 52:48 (or vice versa).
