Through an analysis of  $pK_a$  values for  $HPZ_3^+$ , ionization potentials (IP) for  $PZ_3$ ,  $\nu_{CO}$  for  $\eta-Cp(CO)(PZ_3)Fe(COMe)^0$ , and  $E^\circ$  (229 K) and  $\Delta H^\circ$  for the  $\eta-Cp(CO)(PZ_3)Fe(COMe)^{+0}$  couple, we determined the values of the three electronic parameters,  $\chi_d$ ,  $E_{ar}$  and  $\pi_p$  that are needed to describe the stereoelectronic properties of phosphites. The phenomenon we call the 'aryl effect', which is described by the parameter  $E_{ar}$ , is apparently not restricted to phosphines bearing pendant aryl groups but applies to the phosphites.  $\pi_p$  is a new parameter related to the  $\pi$  acidity of the phosphites. The phosphites studied are listed in terms of increasing  $\pi$  acidity:  $P(OMe)_3 \approx P(OEt)_3 \approx P(OBu)_3 \approx P(O-i-Bu)_3 \approx P(O-i-Pr)_3 < P(OCH_2CH_2Cl)_3 < P(O-p-XC_6H_4)_3 < P(OCH_2)_3CEt$  ( $X = MeO, Me, H, Cl, CN$ ). Using these electronic parameters, along with Tolman's cone angle, we have now incorporated the phosphites into the QALE (quantitative analysis of ligand effects) model and analyzed 32 sets of spectroscopic, thermodynamic, and kinetic data mostly taken from the literature. The analyses give a median  $r^2$  value of 0.982.

## Introduction

Because of the importance of transition metal–phosphorus(III) compounds in catalytic and stoichiometric reactions,<sup>1,2</sup> there is a long standing interest in metal–phosphorus bonding.<sup>1–19</sup> Currently, metal–phosphorus bonding is viewed as being comprised of  $\sigma$ -donation from phosphorus to metal and back donation *via*  $\pi$ -bonding between a filled metal d-orbital and a ligand orbital of appropriate symmetry.<sup>20–25</sup> Theoretical studies are not in agreement about the importance of M–P  $\pi$  bonding. For example, one study suggested that all phosphorus(III) ligands including the  $PR_3$  are good  $\pi$ -acids.<sup>17</sup> Another found that phosphines are poor  $\pi$ -acids whereas  $P(OR)_3$  and particularly  $PF_3$  are good  $\pi$ -acids.<sup>24</sup>

The validation of the theoretical models has remained elusive. The separation of the  $\sigma$  and  $\pi$  components, which is central to understanding M–P bonding, has been attempted empirically<sup>9,10,22,26–39</sup> but the results are not conclusive, although the NMR approach suggested by Alyea<sup>22,26,29–31</sup> might prove fruitful.

Several electronic parameters have been suggested for the phosphorus(III) ligands.<sup>22,26</sup> The  $pK_a$  values<sup>40–43</sup> of  $HPZ_3^+$  are attractive since they are free of the influences of M–P  $\pi$  bonding. The  $pK_a$  values are however, sensitive to the size<sup>44,45</sup> of the phosphorus(III) compounds and are, of course, limited to those  $PZ_3$  which are sufficiently basic that such measurement is possible. Others have proposed spectroscopic properties (NMR<sup>46–50</sup> or IR<sup>51,52</sup>) that are undoubtedly influenced by both the  $\sigma$ -donor and  $\pi$ -acceptor capacity of the ligands.

For the past fifteen years we have been studying linear free energy relationships involving phosphorus(III) compounds *via* the QALE model (quantitative analysis of ligand effects<sup>53–74</sup>). In our original work, we included organophosphites as well as the alkyl and aryl phosphines. Shortly thereafter, we noted that the spectroscopically derived and commonly used electronic parameter,  $\chi$ , cannot be used as a measure of  $\sigma$ -donicity for the phosphites since there is no evidence that  $\chi$  is free of  $\pi$  influences. At the time, we introduced the  $\chi_d$  parameter<sup>45</sup> (based on the  $pK_a$  values  $HPZ_3^+$ ) which we believed was a measure of the  $\sigma$ -donor capacity of these ligands. Unfortunately, we had not

yet discovered the 'aryl effect'<sup>53</sup> and were unaware that, as we show herein, at least four parameters ( $\chi_d$ ,  $\theta$ ,  $E_{ar}$ , and the  $\pi$  acidity parameter,  $\pi_p$ ) are needed to describe the properties of the phosphites. (We find  $E_{ar}$  is not restricted to the  $P(p-XC_6H_4)_3$  ligands and should probably be renamed.) Accordingly these 'old'  $\chi_d$  parameters might have been free of  $\pi$  effects but they are not free of 'aryl effects'. Herein, we introduce a new set of  $\chi_d$  parameters that we believe are free of both  $\pi$  and aryl effects, and indeed describe the  $\sigma$ -donor capacity of the phosphorus(III) ligands. As in the past, we use the Bartik–Tolman  $\chi$  values<sup>51,52</sup> as the  $\chi_d$  values of the  $PR_3$  and  $P(p-XC_6H_4)_3$ , and we continue to assume the absence of M–P  $\pi$  bonding (*i.e.*  $\pi_p = 0$ ) for these phosphines.

## Results and discussion

There is apparently little doubt that phosphites are stronger  $\pi$ -acids than alkyl and aryl phosphines. In the QALE model we assume that  $PR_3$  and  $P(p-XC_6H_4)_3$  have no appreciable  $\pi$ -acidity. We do question, however, whether it is only  $\pi$  acidity that distinguishes phosphites from  $PR_3$ .

To gain insight into the number and nature of parameters needed to describe phosphite ligands, we turn to property *versus* property plots.<sup>62</sup> In the QALE model, each physicochemical property is described by its own equation in terms of the stereoelectronic parameters of the phosphorus(III) ligands. In order to lead the reader through the analysis, we anticipate our results from this paper and give the appropriate form of the QALE equations for two properties ( $prop_1$  and  $prop_2$ ) in the absence of a steric threshold [eqns. (1) and (2)].

$$prop_1 = a_1\chi_d + b_1\theta + c_1E_{ar} + d_1\pi_p + e_1 \quad (1)$$

$$prop_2 = a_2\chi_d + b_2\theta + c_2E_{ar} + d_2\pi_p + e_2 \quad (2)$$

In these equations  $\chi_d$  describes the  $\sigma$  donor capacity,  $\theta$  is Tolman's cone angle which describes the size,<sup>75</sup>  $E_{ar}$  is the aryl effect parameter, and  $\pi_p$  is a measure of the  $\pi$  acidity of the phosphorus(III) ligand. We eliminate  $\chi_d$  between eqns. (1) and (2) and obtain eqn. (3).

$$\text{prop}_1 = \frac{a_1}{a_2} \text{prop}_2 + \left(b_1 - \frac{a_1 b_2}{a_2}\right) \theta + \left(c_1 - \frac{a_1 c_2}{a_2}\right) E_{\text{ar}} + \left(d_1 - \frac{a_1 d_2}{a_2}\right) \pi_{\text{p}} + e_1 - \frac{a_1 e_2}{a_2} \quad (3)$$

For the properties we consider, we can safely take the  $\theta$  contributions to these plots to be small and negligible. Therefore, eqn. (3) becomes eqn. (4).

$$\text{prop}_1 = \frac{a_1}{a_2} \text{prop}_2 + \left(c_1 - \frac{a_1 c_2}{a_2}\right) E_{\text{ar}} + \left(d_1 - \frac{a_1 d_2}{a_2}\right) \pi_{\text{p}} + e_1 - \frac{a_1 e_2}{a_2} \quad (4)$$

For the special case of the  $\text{PR}_3$  ligands, eqn. (4) simplifies to eqn. (5) because both  $E_{\text{ar}}$  and  $\pi_{\text{p}}$  are zero for this family. Thus,

$$\text{prop}_1 = \frac{a_1}{a_2} \text{prop}_2 + e_1 - \frac{a_1 e_2}{a_2} \quad (5)$$

the other ligands differ from  $\text{PR}_3$  due to the  $E_{\text{ar}}$  and/or the  $\pi_{\text{p}}$  terms [compare eqns. (4) and (5)].

In the following example, we use as our properties  $\nu_{\text{CO}}$  for  $\eta\text{-Cp}(\text{CO})(\text{L})\text{Fe}(\text{COMe})^0$ , and  $\Delta H^\circ$  and  $E^\circ$  (229 K) for the  $\text{Cp}(\text{CO})(\text{L})\text{Fe}(\text{COMe})^{+10}$  couple, all of which have been measured in our laboratories. The appropriate data are displayed in Tables 1 and 2. In the plot of  $\nu_{\text{CO}}$  versus  $E^\circ$  (229 K) (Fig. 1A), we see a set of parallel lines. The parallel nature of the lines indicates that both properties are responding to a single variable parameter that is common to all the ligands. In the QALE model this parameter is  $\chi_{\text{d}}$ . Although the lines have the same slopes they have different intercepts which demands that the remaining parameters differ from family to family by a constant value. For example, in Fig. 1A, the line for  $\text{P}(p\text{-XC}_6\text{H}_4)_3$  lies below the line for  $\text{PR}_3$  because of the 'aryl effect' which is constant (2.7) for  $\text{P}(p\text{-XC}_6\text{H}_4)_3$  and zero for  $\text{PR}_3$ . ( $\pi_{\text{p}}$  is assumed to be zero for both  $\text{P}(p\text{-XC}_6\text{H}_4)_3$  and  $\text{PR}_3$ .) Notice that the  $\text{P}(\text{OR})_3$  and  $\text{P}(\text{O-}p\text{-XC}_6\text{H}_4)_3$  lie on two lines on the **other side** of the  $\text{PR}_3$  line and the point for  $\text{P}(\text{OCH}_2)_3\text{CET}$  lies above all the lines. This pattern of lines could be described by eqn. (6) without invoking

$$\text{prop}_1 = \frac{a_1}{a_2} \text{prop}_2 + \left(c_1 - \frac{a_1 c_2}{a_2}\right) E_{\text{ar}} + e_1 - \frac{a_1 e_2}{a_2} \quad (6)$$

a  $\pi$  effect provided that the phosphites possess negative values of the 'aryl effect' parameter,  $E_{\text{ar}}$ . If this be the case, then the lines for the phosphites and  $\text{P}(p\text{-XC}_6\text{H}_4)_3$  should always lie on opposite sides of the  $\text{PR}_3$  line in the absence of a steric effect.

However, we observe a different ordering of the lines, when we plot  $\nu_{\text{CO}}$  versus  $\Delta H^\circ$ . In this case **all the lines lie below** the  $\text{PR}_3$  line. Thus, the deviation of the phosphite data from the  $\text{PR}_3$  lines is not explainable in terms of eqn. (6) along with a negative aryl effect for the phosphites. Let us see if the deviation of the phosphites is explainable in terms of a new  $\pi$  parameter,  $\pi_{\text{p}}$ , only [eqn. (7)].

$$\text{prop}_1 = \frac{a_1}{a_2} \text{prop}_2 + \left(d_1 - \frac{a_1 d_2}{a_2}\right) \pi_{\text{p}} + e_1 - \frac{a_1 e_2}{a_2} \quad (7)$$

Thus according to eqn. (7), the deviation of the lines for the phosphites (Fig. 1A) from the  $\text{PR}_3$  line would be attributable to  $\pi$  effects. This same pattern of lines ( $\text{PR}_3$ ,  $\text{P}(\text{OR})_3$ ,  $\text{P}(\text{O-}p\text{-XC}_6\text{H}_4)_3$ ,  $\text{P}(\text{OCH}_2)_3\text{CET}$ ) must then be observed for each property versus property plot. In Fig. 1B, we see that this is not the case, the point for  $\text{P}(\text{OCH}_2)_3\text{CET}$  lies on the  $\text{PR}_3$  line and the points for  $\text{P}(\text{OR})_3$  and  $\text{P}(\text{O-}p\text{-XC}_6\text{H}_4)_3$  lie on a single line below the line for  $\text{PR}_3$ . Thus, we conclude that at least two parameters, in addition to  $\chi_{\text{d}}$  and  $\theta$ , are required to describe the phosphites.

**Fig. 1** (A)  $\nu_{\text{CO}}$  ( $-1900 \text{ cm}^{-1}$ ) versus  $E^\circ$  (229 K), (B)  $\nu_{\text{CO}}$  ( $-1900 \text{ cm}^{-1}$ ) versus  $\Delta H^\circ$ , (C)  $\nu_{\text{CO}}$  (calc) versus  $E^\circ$  (229 K), and (D)  $\nu_{\text{CO}}$  (calc) versus  $\Delta H^\circ$ . Values of  $\nu_{\text{CO}}$ ,  $E^\circ$  (229 K), and  $\Delta H^\circ$  are taken from Tables 1 and 2.  $\nu_{\text{CO}}$  (calc) were calculated via regression analysis using the  $E_{\text{ar}}$  and  $\pi_{\text{p}}$  parameters presented in Table 1 via eqn. (4) where  $\text{prop}_2$  is  $E^\circ$  (229 K) (Fig. 1C) or  $\Delta H^\circ$  (Fig. 1D). The sets of ligands are represented in the following way:  $\text{PR}_3$  (filled squares),  $\text{P}(p\text{-XC}_6\text{H}_4)_3$  (open circles),  $\text{P}(\text{OR})_3$  (filled triangles) and  $\text{P}(\text{O-}p\text{-XC}_6\text{H}_4)_3$  (open triangles).  $\text{P}(\text{OCH}_2\text{CH}_2\text{Cl})_3$  is not included in this analysis.

Applying Occam's razor, we make the assumption that the first additional parameter for the phosphites is  $E_{\text{ar}}$  which apparently describes a property not restricted to aryl phosphines. For historical reasons and the sake of continuity we will retain the symbol  $E_{\text{ar}}$  to describe this effect. The second additional parameter ( $\pi_{\text{p}}$ ) is then attributed to a  $\pi$  interaction between the phosphites and the metal to which they are attached. As pointed out above, the parallel lines in Figs. 1A and 1B require that  $E_{\text{ar}}$  and  $\pi_{\text{p}}$  be virtually constant for each family.

We are now ready to determine the values of  $E_{\text{ar}}$  and  $\pi_{\text{p}}$  for the phosphites. In eqn. (1), we can obtain the coefficients 'a', 'b', 'c' and 'e' through analysis of the data for the  $\text{PR}_3$  and  $\text{P}(p\text{-XC}_6\text{H}_4)_3$ , alone. Since in the QALE model these coefficients should not change as new sets of ligands are added to the analysis, these coefficients are appropriate for the analysis of data for the phosphites; however, we do not know the values of  $\chi_{\text{d}}$ ,  $E_{\text{ar}}$ , nor  $\pi_{\text{p}}$  and its coefficient 'd' in eqn. (1). We now present a way to determine  $\chi_{\text{d}}$  and  $E_{\text{ar}}$  values of the phosphites.

We make use of two properties that can be reasonably assumed to be independent of metal-phosphorus  $\pi$ -bonding. These properties are  $\text{p}K_{\text{a}}$  values of  $\text{HPZ}_3^+$ , and the ionization potential of  $\text{PZ}_3$  as determined by photoelectron spectroscopy. Since  $\pi$ -bonding is not involved, the regression equations that describe these properties in terms of  $\chi_{\text{d}}$ ,  $\theta$ , and  $E_{\text{ar}}$  for the phosphines (entries 1 and 2 in Table 3) must also be applicable to the phosphites as well. Using the experimental values and Tolman's cone angles for the  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{CET}$ , we solved the two simultaneous equations (entries 1 and 2 in Table 3) to obtain initial values of  $\chi_{\text{d}}$  (17.7 and 20.0 respectively) and  $E_{\text{ar}}$  (1.0 and 0.12, respectively). These initial values are used in an iterative process to arrive at the final values of  $\chi_{\text{d}}$  and  $E_{\text{ar}}$  for these ligands.

The next step is to get an estimate of the  $\pi$  parameters for  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{CET}$ . From the analysis of  $\Delta S^\circ$  and  $\Delta H^\circ$  for the  $\eta\text{-Cp}(\text{CO})(\text{L})\text{Fe}(\text{COMe})^{+10}$  couple we know that the aryl effect in  $\Delta G^\circ$  vanishes at 320 K (the  $E_{\text{ar}}$  isoequilibrium temperature<sup>83-86</sup>). Thus, we calculated  $\Delta G^\circ$  (320 K) and analyzed the data for the phosphines in terms of  $\chi_{\text{d}}$  and  $\theta$  only (entry 6, Table 3). We then subtracted  $b\theta$  from the calculated  $\Delta G^\circ$  (320 K) for the phosphines as well as  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{CET}$  and plotted the difference versus  $\chi_{\text{d}}$  (Fig. 2). The

**Table 1** Ligands (PZ<sub>3</sub>) used in this study,  $\nu_{\text{CO}}$  for  $\eta\text{-Cp}(\text{CO})(\text{PZ}_3)\text{Fe}(\text{COMe})^0$  where PZ<sub>3</sub> has formally C<sub>3</sub> symmetry, and stereoelectronic parameters ( $\chi_{\text{d}}$ ,  $\theta$ ,  $E_{\text{ar}}$ ,  $\pi_{\text{p}}$ ) of the phosphorus(III) ligands considered in this paper. The values of parameters shown in italics were determined by a least squares analysis as described in the text and the footnotes to this table

<sup>a</sup>  $\nu_{\text{CO}}$  (cm<sup>-1</sup>) values were measured in cyclohexane. The error is estimated to be  $\pm 0.2$  cm<sup>-1</sup>. <sup>b</sup> The  $\chi_{\text{d}}$  values for the phosphites are reported in this paper. The  $\chi_{\text{d}}$  values for the mixed alkyl phenyl phosphines are taken from ref. 83. The  $\chi_{\text{d}}$  values for PR<sub>3</sub> and P(*p*-XC<sub>6</sub>H<sub>4</sub>)<sub>3</sub> are taken from ref. 52. <sup>c</sup> Tolman's cone angles are taken from ref. 51. <sup>d</sup>  $E_{\text{ar}}$  values are taken from refs. 53 and 83. <sup>e</sup> The  $\pi_{\text{p}}$  values for the phosphites are reported in this paper. <sup>f</sup> The least squares analyses were carried out in the following manner. First, the 'd' coefficients were determined by regression analysis [via eqn. (1)] of sets of data ( $\Delta H^\circ$ ,  $E^\circ$  (229),  $\nu_{\text{CO}}$ , Bodner's  $\delta$  values,  $\text{p}K_{\text{a}}$ , and IP) comprised of the phosphines plus P(OMe)<sub>3</sub> and P(OCH<sub>2</sub>)<sub>3</sub>CEt. Employing Tolman's cone angles and using a least squares program, we then found the best fit values for  $\chi_{\text{d}}$ ,  $E_{\text{ar}}$ , and  $\pi_{\text{p}}$  for the phosphites. Combinations selected from these six sets of equations were used in the least squares analyses for the other phosphites as described below. <sup>g</sup> Regression equations for  $\Delta H^\circ$ ,  $E^\circ$  (229),  $\nu_{\text{CO}}$ , Bodner's  $\delta$  values,  $\text{p}K_{\text{a}}$ , and IP were used in the least squares analysis. <sup>h</sup> Regression equations for  $\Delta H^\circ$ ,  $E^\circ$  (229),  $\nu_{\text{CO}}$  and Bodner's  $\delta$  values were used in the least squares analysis. <sup>i</sup> Regression equations for  $\Delta H^\circ$ ,  $E^\circ$  (229),  $\nu_{\text{CO}}$ , Bodner's  $\delta$  values and  $\text{p}K_{\text{a}}$  were used in the least squares analysis. <sup>j</sup> Multiple  $\nu_{\text{CO}}$  were observed. <sup>k</sup> Regression equations for  $\Delta H^\circ$ ,  $E^\circ$  (229), Bodner's  $\delta$  values and  $\text{p}K_{\text{a}}$  were used in the least squares analysis.

deviation of the phosphite data from the line determined by the phosphines is a measure of the  $\pi$  acidity (and therefore  $\pi_{\text{p}}$ ) of the phosphites. We arbitrarily set  $\pi_{\text{p}} = 3.0$  for P(OMe)<sub>3</sub> and then calculated a value of  $\pi_{\text{p}} = 5.0$  for P(OCH<sub>2</sub>)<sub>3</sub>CEt.

We still need the values of 'd' (equations 1 and 2) for a given property. In the QALE model the addition of a new parameter (*i.e.*  $\pi_{\text{p}}$ ) should not change significantly the coefficients of the other parameters. Thus, incorporation of the data for P(OMe)<sub>3</sub> and P(OCH<sub>2</sub>)<sub>3</sub>CEt along with PR<sub>3</sub> and P(*p*-XC<sub>6</sub>H<sub>4</sub>)<sub>3</sub> into analysis of the aforementioned  $\Delta H^\circ$ ,  $\nu_{\text{CO}}$ , and  $E^\circ$  (229) should leave the coefficients 'a', 'b', 'c' and 'e' unchanged and give an esti-

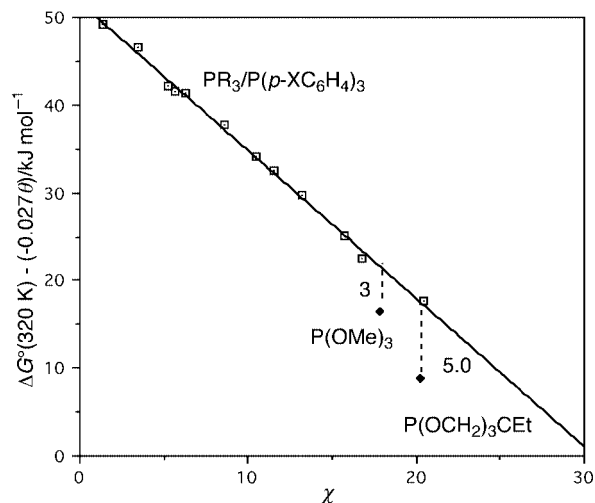

mate of the respective 'd' coefficients. Examination of entries 3, 6, 9 (phosphines only) and 4, 7, 10 (phosphines, P(OMe)<sub>3</sub> and P(OCH<sub>2</sub>)<sub>3</sub>CEt) in Table 3 shows that indeed this is very nearly the case. We now generate the first iteration of the QALE equations (entries 5, 8, and 11 in Table 3) for  $\Delta H^\circ$ ,  $E^\circ$  (229 K) and  $\nu_{\text{CO}}$  by taking entries 3, 6 and 9 and adding to them the respective  $d\pi_{\text{p}}$  term from entries 4, 7, and 10.

We now solve simultaneously the three QALE equations (entries 5, 8, and 11 in Table 3) for P(OMe)<sub>3</sub> and P(OCH<sub>2</sub>)<sub>3</sub>CEt in terms of the parameters  $\chi_{\text{d}}$ ,  $E_{\text{ar}}$ , and  $\pi_{\text{p}}$ . This gives values (which we use in subsequent analyses) for P(OMe)<sub>3</sub> ( $\chi_{\text{d}} = 17.9$ ,

<sup>a</sup> Errors are  $\pm 0.0007$  V. <sup>b</sup> The numbers refer to the entries in Table 1.

**Fig. 2** A plot of  $\Delta G^\circ(320 \text{ K}) - (-0.027\theta)$  versus  $\chi_d$  for  $\text{PR}_3$  and  $\text{P}(p\text{-XC}_6\text{H}_4)_3$ . The deviation of the points for  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{Cet}$  from the line is a measure of their  $\pi$  acidity ( $\pi_p$ ).

$E_{\text{ar}} = 1.0$ ,  $\pi_p = 2.8$ ) and  $\text{P}(\text{OCH}_2)_3\text{Cet}$  ( $\chi_d = 20.2$ ,  $E_{\text{ar}} = 0.2$ ,  $\pi_p = 5.0$ ). These values are quite similar to what we estimated initially and give us confidence that we can determine the parameters for the other phosphites by solving the same set of simultaneous equations using the appropriate experimental data. (We had to substitute the  $pK_a$  eqn. (entry 1 in Table 3) for the  $\nu_{\text{CO}}$  equation for  $\text{P}(\text{O}-i\text{-Pr})_3$  since three  $\nu_{\text{CO}}$  were observed for  $\eta\text{-Cp}(\text{CO})[\text{P}(\text{O}-i\text{-Pr})_3]\text{FeCOMe}$ .) The calculated parameters are displayed in Table 1.

We point out that the results are not particularly sensitive to the value of  $\theta$  used in the simultaneous equations. For example, we show in Table 4 the calculated values of  $\chi$ ,  $E_{\text{ar}}$ , and  $\pi_p$  using different values of  $\theta$ . The results, which are shown in Table 4 for  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{O}-i\text{-Bu})_3$ , reveal minor changes in the parameters over a range of  $20^\circ$  in  $\theta$ .

We checked the validity of the phosphite parameters by using a linear regression analysis of combinations of six sets of data ( $\Delta H^\circ$ ,  $E^\circ$  (229 K),  $\nu_{\text{CO}}$ , Bodner's  $\delta$  values,  $pK_a$  values of  $\text{HPZ}_3^+$ , and IP of  $\text{PZ}_3$ ). We did the analysis in the following manner. Using the experimental data and the parameters for the phosphines and  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{Cet}$  (our standard phosphites) we performed the regression analyses on each of the six properties in order to establish the 'd' coefficients for each of the regression equations. We then took the six regression equations and did a least squares analysis to determine the best fit values of  $\chi_d$ ,  $E_{\text{ar}}$ , and  $\pi_p$  for  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{Cet}$ . Not surprisingly, the least squares analysis gave values for  $\text{P}(\text{OMe})_3$  and  $\text{P}(\text{OCH}_2)_3\text{Cet}$  (presented in italics in Table 1) in excellent agreement with the original parameters. We then performed the least squares analyses on combinations of these properties (see footnotes for Table 1) for other phosphites

( $\text{P}(\text{OEt})_3$ ,  $\text{P}(\text{OBu})_3$ ,  $\text{P}(\text{OCH}_2\text{CH}_2\text{Cl})_3$ ,  $\text{P}(\text{O}-\text{C}_6\text{H}_5)_3$ , and  $\text{P}(\text{O}-i\text{-Pr})_3$ ) where we have sufficient data. The values of the parameters thereby obtained, are in excellent agreement with the parameters obtained *via* the simultaneous equations. The one exception is  $\text{P}(\text{OBu})_3$  where the linear regression analysis gives results that are quite different from the parameters for  $\text{P}(\text{OEt})_3$ . Normally,  $\text{P}(\text{OBu})_3$  and  $\text{P}(\text{OEt})_3$  behave similarly—therefore we believe that Bodner's  $\delta$  value for  $\text{P}(\text{OBu})_3$  is anomalous.

An examination of the  $\chi_d$  and  $\pi_p$  parameters for the phosphites is insightful. The  $\chi_d$  values of the  $\text{P}(\text{OR})_3$  indicate that their  $\sigma$  donor capacities are as good as those for  $\text{P}(p\text{-XC}_6\text{H}_4)_3$ . This observation is consonant with the similarity of the  $pK_a$  values of  $\text{P}(\text{OR})_3$  and  $\text{P}(p\text{-XC}_6\text{H}_4)_3$ . The  $\pi$  acidity of the  $\text{P}(\text{OR})_3$  is almost invariant, ranging between 2.7 and 3.0. This is in agreement with our analysis of Fig. 1. There are two exceptions:  $\text{P}(\text{OCH}_2\text{CH}_2\text{Cl})_3$ , which displays an enhanced  $\pi$  acidity,  $\pi_p = 3.6$ , and  $\text{P}(\text{OCH}_2)_3\text{Cet}$ , which is a reasonably good electron donor ( $\chi_d = 20.2$ ) (not much different than  $\text{P}(\text{OMe})_3$ ,  $\chi_d = 17.9$ ) and a strong  $\pi$  acid ( $\pi_p = 5.0$ ).

$\text{P}(\text{O}-p\text{-XC}_6\text{H}_4)_3$  are poorer  $\sigma$  donors than  $\text{P}(\text{OR})_3$ . Their  $\sigma$  donor capacity is influenced by the *para* substituent in the expected manner with  $\text{P}(\text{O}-p\text{-MeOC}_6\text{H}_4)_3$  and  $\text{P}(\text{O}-p\text{-MeC}_6\text{H}_4)_3$  being the best  $\sigma$  donors and  $\text{P}(\text{O}-p\text{-NCC}_6\text{H}_4)_3$  being the poorest. It is noteworthy that the  $\pi$ -acidity of the aryl phosphites appears to be almost invariant with  $\pi_p$  ranging between 3.7 and 4.2 again in agreement with the analysis of Fig. 1.

$\text{P}(\text{O}-p\text{-XC}_6\text{H}_4)_3$  and most  $\text{P}(\text{OR})_3$  exhibit significant 'aryl effects' that are relatively invariant, with  $E_{\text{ar}}$  values between 1.0 and 1.4. The smallest aryl effects are observed for  $\text{P}(\text{OCH}_2)_3\text{Cet}$  and  $\text{P}(\text{OCH}_2\text{CH}_2\text{Cl})_3$  ( $E_{\text{ar}} = 0.2$  and 0.4 respectively).

We used the parameters in Table 1 and eqn. (4) to calculate the data necessary to simulate property *versus* property plots shown Figs. 1A and 1B. The results, which are displayed in Figs. 1C and 1D, are virtually identical to Figs. 1A and 1B.

We recently described another diagnostic test for adequacy of a set of stereoelectronic parameters.<sup>86</sup> If a set of parameters adequately describes the stereoelectronic properties of phosphorus(III) ligands, then the regression equations resulting from the use of these parameters in the analysis of  $\Delta H^\circ$ ,  $\Delta S^\circ$  and/or  $E^\circ$  must be able to reproduce the experimental graph of  $E^\circ/T$  *versus*  $1/T$ . Although the parameters for the phosphites are in part based on  $\Delta H^\circ$  and  $\Delta S^\circ$  (this would lead to circular reasoning if this were the only input), they also have input from  $\nu_{\text{CO}}$ ,  $pK_a$ , and IP (as described earlier), which are independent of  $\Delta H^\circ$  and  $\Delta S^\circ$ . In Fig. 3, we compare the plots of experimental and calculated  $E^\circ/T$  *versus*  $1/T$ . Clearly, they are virtually the same; thus, we conclude that the parameters are valid descriptors.

We used these new phosphite parameters to analyze (*via* eqn. 8, where  $\theta_{\text{st}}$  is the steric threshold and  $\lambda$  is the switching

$$\text{prop} = a\chi + b(\theta - \theta_{\text{st}})\lambda + cE_{\text{ar}} + d\pi_p + e \quad (8)$$

**Table 3** Results of the regression analyses of the properties indicated below. function) 32 sets of data that are large enough to support a four parameter analysis (or a five parameter analysis if a steric threshold were present). We used all the parameters in each analysis even though in some cases the contribution of one or more parameters is statistically indistinguishable from zero. The results of these analyses are presented in Table 6. We note that out of nearly 600 data, we found only twelve outliers. There is an excellent fit of the QALE model to each set of data with a median *r*<sup>2</sup> of 0.980.

These analyses give chemically reasonable results (see Table 5 and Table 6). *v*<sub>CO</sub> increases as the  $\pi$  acidity of the phosphorus(III) ligand increases, and decreases as the  $\sigma$  donicity increases. *v*<sub>CO</sub> is relatively insensitive to steric effects. Δ*S*<sup>o</sup> and Δ*H*<sup>o</sup> for the reduction of  $\eta$ -Cp(CO)(L)Fe(COMe)<sup>+</sup> both become more negative as the  $\pi$  acidity of the phosphorus(III) ligand increases (entries 19 and 20). These observations suggest that  $\pi$  acidity is more important in the Fe(II) state than in the Fe(III) state and that the enhanced  $\pi$  bonding increases the rigidity of the Fe(II) complex. The dissociation of CO from ruthenium complexes is dominated by steric factors which accelerate the reaction as the size of the ancillary phosphorus(III) ligand increases (entries 27 and 28). The entering ligand dependent substitution reactions (entries 29–32) are all accelerated as the  $\sigma$  donicity of the phosphorus(III) ligand increases and inhibited as the size of the entering ligand increases. There is virtually no statistically significant evidence for a  $\pi$  effect in these reactions.

The one surprising result is that the rate of addition of PZ<sub>3</sub> to ( $\eta^5$ -C<sub>6</sub>H<sub>7</sub>)Fe(CO)<sub>3</sub><sup>+</sup> shows a large inhibition because of  $\pi$ -effects. On the other hand, the rate is enhanced by increasing  $\sigma$  donicity and inhibited by increasing size as expected.

<sup>a</sup> The percent contribution of a parameter to the property. This was determined by multiplying the coefficient of the parameter by the range of the parameter. The result is divided by the sum of all the products of coefficient times range.

## Conclusions

We have determined values for  $\chi_d$ ,  $E_{ar}$ , and  $\pi_p$  of phosphite ligands.  $\chi_d$  for P(OR)<sub>3</sub> depends on the nature of the pendent alkoxy group whereas the  $\pi$  acidity is relatively invariant except for P(OCH<sub>2</sub>CH<sub>2</sub>Cl)<sub>3</sub> and P(OCH<sub>2</sub>)<sub>3</sub>CEt; the latter ligand is the most  $\pi$  acidic ligand considered in this study.  $\chi_d$  for P(O-*p*-XC<sub>6</sub>H<sub>4</sub>)<sub>3</sub> is dependent on the *para* substituent whereas  $\pi_p$  appears to be invariant and independent of the *para* substituent. With identification of the parameters needed to describe the stereoelectronic properties of the phosphite ligands, and the determination of their values, we have incorporated the phosphites into the QALE model. Thus, QALE now accommodates PR<sub>3</sub> (including the large ligands such as PCy<sub>3</sub>), P(*p*-XC<sub>6</sub>H<sub>4</sub>)<sub>3</sub>, PPh<sub>3</sub>R<sub>3-*i*</sub>, and the  $\pi$  acidic ligands P(OR)<sub>3</sub> and P(O-*p*-XC<sub>6</sub>H<sub>4</sub>)<sub>3</sub>. We point out that the QALE model is general and applicable to the analysis of kinetic, spectroscopic and thermodynamic properties including entropy. We report the QALE analyses (median  $r^2 = 0.982$ ) of 32 sets of data.

We are currently extending these studies to other  $\pi$  acidic ligands.

## Experimental

### General procedures

All manipulations and preparations were carried out under argon using standard techniques. Acetonitrile (J. T. Baker HPLC grade), which was purified by distillation from P<sub>2</sub>O<sub>5</sub>, was then kept refluxing over CaH<sub>2</sub> and distilled immediately prior to use. Tetrabutylammonium hexafluorophosphate (TBAH) (Aldrich) was recrystallized from warm ethyl acetate; before use it was heated *in vacuo* to remove residual solvent. The phosphines (Aldrich, Lancaster and Strem) were used as received. The  $\eta$ -Cp(CO)(L)Fe(COMe) complexes were synthesized according to literature methods.<sup>43</sup>

The  $E^\circ$  values for the  $\eta$ -Cp(CO)(L)Fe(COMe)<sup>+0</sup> couple were obtained *via* cyclic voltammetry, and were measured relative to acetylferrocene. Since there was no significant decomposition of the electrochemically generated species, the  $E^\circ$  values could be obtained by averaging the voltage of the peak potentials of the cyclic voltammogram. Each measurement was taken between 5 and 10 times. The measurements were then repeated with a fresh sample and found to agree with the original measurements. This leads to an error of  $\pm 0.0007$  V in the  $E^\circ$  values.

- 75 A number of parameters describing the size of phosphorus ligands have been proposed including Coville and White's solid angle (references 76–79), Brown's Er values (references 12–14, 16, 80) and Tolman's cone angles (reference 51). Although Ernst (references 81, 82) has suggested some revision of Tolman's cone angles, we have found that Tolman's values give the best results in regression analyses.
