

## Electrophilic Behaviour of the Co-ordinated Nitrosyl Cation: Reactions of Pentahalogenonitrosyliridate(1-)

By Frank Bottomley,\* Steven G. Clarkson, and (in part), Shiu-Bor Tong, Department of Chemistry, University of New Brunswick, Fredericton, New Brunswick E3B 5A3, Canada

The complexes  $[\text{Ir}(\text{X})_5\text{NO}]^-$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) are attacked at the nitrosyl nitrogen atom by nucleophiles according to the equations: (i)  $[\text{Ir}(\text{X})_5\text{NO}]^- + 2\text{OH}^- \rightleftharpoons [\text{Ir}(\text{X})_5\text{NO}_2]^{3-} + \text{H}_2\text{O}$ ; (ii)  $[\text{Ir}(\text{X})_5\text{NO}]^- + \text{NH}_2\text{OH} \longrightarrow [\text{Ir}(\text{X})_5\text{H}_2\text{O}]^{2-} + \text{N}_2\text{O} + \text{H}^+$ ; (iii)  $[\text{Ir}(\text{X})_5\text{NO}]^- + \text{N}_3^- + \text{H}_2\text{O} \longrightarrow [\text{Ir}(\text{X})_5\text{H}_2\text{O}]^{2-} + \text{N}_2\text{O} + \text{N}_2$ ; and (iv)  $[\text{Ir}(\text{X})_5\text{NO}]^- + 2\text{NH}_3 \longrightarrow [\text{Ir}(\text{X})_5\text{NH}_3]^{2-} + \text{N}_2 + \text{H}_3\text{O}^+$ . Hydrazine hydrate and  $[\text{Ir}(\text{Br})_5\text{NO}]^-$  form  $[\text{IrBr}_3(\text{N}_2\text{H}_4)_3] \cdot 0.5\text{H}_2\text{O}$  by an unknown route. Equilibrium constants for the reversible reaction with  $\text{OH}^-$  are compared with the analogous reactions of  $\text{NO}^+$  and  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$ .

In the last few years there has been an increasing interest in the reactivity of co-ordinated  $\text{NO}^+$ ,<sup>1-13</sup> and the long known, but apparently anomalous, behaviour of the ion  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$  towards  $\text{OH}^-$  (ref. 1) has been shown to be one example of a rather general class of reactions. However, other examples have been rather scattered and in addition several unsuccessful attempts at nucleophilic attack at co-ordinated  $\text{NO}^+$  have been reported.<sup>12,14-16</sup> We recently proposed that complexes containing  $\text{NO}^+$  having  $\bar{\nu}(\text{NO})$  greater than *ca.*  $1\ 886\ \text{cm}^{-1}$  [or  $f(\text{N}-\text{O})$  greater than  $13.8\ \text{mdyn}\ \text{\AA}^{-1}$ ] † would be susceptible to nucleophilic attack at the nitrosyl nitrogen atom.<sup>17</sup> The complexes  $[\text{Ir}(\text{X})_5\text{NO}]^-$ <sup>18,19</sup> [ $\text{X} = \text{Cl}$ ,  $\bar{\nu}(\text{NO}) = 2\ 008\ \text{cm}^{-1}$ ;  $\text{X} = \text{Br}$ ,  $\bar{\nu}(\text{NO}) = 1\ 953\ \text{cm}^{-1}$ ] clearly provide an excellent test of this idea,  $[\text{Ir}(\text{Cl})_5\text{NO}]^-$  having the highest  $\bar{\nu}(\text{NO})$  value yet reported for a nitrosyl complex. The high  $\bar{\nu}(\text{NO})$  frequencies also provide assurance that the complexes formally contain  $\text{NO}^+$  rather than  $\text{NO}^-$ .<sup>20</sup> We have therefore investigated reactions of the ions  $[\text{Ir}(\text{X})_5\text{NO}]^-$  with the nucleophiles  $\text{NH}_3$ ,  $\text{N}_3^-$ ,  $\text{N}_2\text{H}_4$ ,  $\text{NH}_2\text{OH}$ , and  $\text{H}_2\text{O}$  and report the results in detail here.

### RESULTS AND DISCUSSION

The deep-red ions  $[\text{Ir}(\text{X})_5\text{NO}]^-$  were largely present only in very acidic ( $[\text{H}^+] > 0.5\text{M}$ ) solutions. ‡ In neutral or alkaline solutions they converted to  $[\text{Ir}(\text{X})_5\text{NO}_2]^{3-}$ , which could be precipitated out with ethanol. Equilibrium constants for the reactions (I) are compared with  $[\text{Ir}(\text{X})_5\text{NO}]^- + 2\text{OH}^- \rightleftharpoons [\text{Ir}(\text{X})_5\text{NO}_2]^{3-} + \text{H}_2\text{O}$  (I)

similar reactions of  $\text{NO}^+$  and  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$  in the Table. The constants were determined spectrophotometrically at  $25\ ^\circ\text{C}$  and  $I = 1.0\text{M}$ , and were quite reproducible. The value for  $[\text{Ir}(\text{Cl})_5\text{NO}]^-$  is an estimate because it was

†  $1\ \text{dyn} = 10^{-5}\text{N}$ .

‡  $1\text{M} = 1\ \text{mol}\ \text{dm}^{-3}$ .

impossible to obtain a solution of sufficient acidity (without decomposing the complex) to convert all the complex to the nitrosyl form. This demonstrates the ease of nucleophilic attack at  $[\text{Ir}(\text{Cl})_5\text{NO}]^-$ . The electronic

Equilibrium constants for reaction (I)		
Ion	$K/l^2\ \text{mol}^{-2}$	$\bar{\nu}(\text{NO})/\text{cm}^{-1}$
$\text{NO}^+$	$2.3 \times 10^{31}$ (ref. 1)	2 220
$[\text{Ir}(\text{Cl})_5\text{NO}]^-$	$> 6 \times 10^{29}$	2 008
$[\text{Ir}(\text{Br})_5\text{NO}]^-$	$6.8 \times 10^{27}$	1 953
$[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$	$1.5 \times 10^6$ (ref. 1)	1 938

spectrum of the ion  $[\text{Ir}(\text{Cl})_5\text{NO}_2]^{3-}$  was not suitable for accurate determination of its concentration. Even for  $[\text{Ir}(\text{Br})_5\text{NO}]^-$  the high acidity required to obtain the nitrosyl form limited the range of concentration over which the equilibrium constants could be measured. This is known to produce errors.<sup>21</sup>

Even allowing for these limitations the contrast between the  $K$  values for  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$  and  $[\text{Ir}(\text{X})_5\text{NO}]^-$  shown in the Table is striking, and indicates the electron density at the nitrosyl nitrogen atom in the ion  $[\text{Ir}(\text{X})_5\text{NO}]^-$  is much closer to that in  $\text{NO}^+$  than to that in  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$ , despite the formal similarity of the complexes. However, in the i.r. spectra,  $\bar{\nu}(\text{NO})$  of  $\text{NO}^+$  is over  $200\ \text{cm}^{-1}$  greater than for any of the complexes, for which there is a spread of only  $50\ \text{cm}^{-1}$ . It has been pointed out that for CO and  $\text{N}_2$  the decrease in  $\bar{\nu}(\text{CO})$  or  $\bar{\nu}(\text{N}_2)$  on co-ordination is a function not only of the energy of the ligand  $\pi$ -acceptor orbitals but also of the energy of the ligand orbital involved in  $\sigma$ -bonding to the metal atom.<sup>22</sup> For CO this latter orbital is slightly antibonding, whereas for  $\text{N}_2$  it is bonding,<sup>22</sup> and calculations here indicate it is bonding for  $\text{NO}^+$  also. § Donation of electrons from  $\text{NO}^+$  to the metal decreases the electron density at the nitrogen atom and decreases  $\bar{\nu}(\text{NO})$ ; back donation of metal electrons to  $\text{NO}^+$  antibonding orbitals

increases the electron density and decreases  $\nu(\text{NO})$ . Hence the electron density in a  $\text{NO}^+$  complex can be similar to that of  $\text{NO}^+$ , despite the  $200\text{ cm}^{-1}$  difference in  $\bar{\nu}(\text{NO})$ . Comparing the ions  $[\text{Ir}(\text{X})_5\text{NO}]^-$  and  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$ , the difference in electron density is much more closely related to the  $\pi$ -acceptor function of the ligand, and hence to  $\nu(\text{NO})$ . It is clear from the large difference in  $K$  values but small difference in  $\bar{\nu}(\text{NO})$  that the i.r. spectra are a very coarse measure of electron density. This is further illustrated when  $[\text{Fe}(\text{CN})_5\text{NO}]^{2-}$  is compared with  $[\text{RuCl}(\text{bipy})_2\text{NO}]^{2+}$ , for which  $\bar{\nu}(\text{NO})$  is  $1927\text{ cm}^{-1}$  but  $K$  is  $1.6 \times 10^9$ .<sup>6</sup>

On setting aside in neutral solution, the ion  $[\text{Ir}(\text{X})_5\text{NO}_2]^{3-}$  underwent ligand substitution and  $[\text{IrBr}_4(\text{NO}_2)\text{H}_2\text{O}]^{2-}$  was isolated from such a solution. This behaviour is not found for  $[\text{Ir}(\text{X})_5\text{NO}]^-$ , and must be due to the *trans*-labilising influence of  $\text{NO}_2^-$ ; <sup>23,24</sup>  $\text{NO}^+$  exerts an opposite influence in related complexes.<sup>25</sup>

Reactions of the ion  $[\text{Ir}(\text{Br})_5\text{NO}]^-$  with aqueous  $\text{NH}_2\text{OH}$ ,  $\text{N}_3^-$ , or  $\text{NH}_3$  were instantaneous. All gaseous as well as iridium-containing products were investigated, and the reactions are represented by equations (2)–(4). Less-detailed investigation of reactions of the ion  $[\text{Ir}(\text{Cl})_5\text{NO}]^-$  indicates analogous behaviour. Despite

the alkaline nature of the reaction solutions,  $[\text{Ir}(\text{Br})_5\text{H}_2\text{O}]^{2-}$  (ref. 26) and  $[\text{Ir}(\text{Br})_5\text{NH}_3]^{2-}$  (ref. 27) were obtained cleanly, with no evidence for  $[\text{Ir}(\text{Br})_5\text{OH}]^{3-}$  or other hydroxo-iridium complexes. Reaction (2) is presumed to occur in the same way as that between  $[\text{Ru}(\text{NH}_3)_5\text{NO}]^{3+}$  and  $\text{NH}_2\text{OH}$ , *i.e.* by initial attack of  $\text{NH}_2\text{OH}$  at the nitrosyl N atom.<sup>5,11</sup> The resultant ion  $[\text{Ir}(\text{Br})_5\text{N}_2\text{O}]^{2-}$  must decompose rapidly, as does  $[\text{Ru}(\text{NH}_3)_5\text{N}_2\text{O}]^{2+}$ .<sup>11</sup> Reaction (3) has previous analogues in the reactions of  $[\text{RuCl}(\text{L})_2\text{NO}]^{2+}$  [ $\text{L} = o$ -phenylenebis(dimethylarsine), 2,2'-bipyridine (bipy), or 1,10-phenanthroline] with  $\text{N}_3^-$ .<sup>7,9</sup> As here,  $\text{N}_2$  and  $\text{N}_2\text{O}$  are evolved, and a reasonable mechanism for the reaction, involving initial attack of  $\text{N}_3^-$  at the nitrosyl, has been proposed.<sup>9</sup> Reaction (4) has no direct analogue, though co-ordinated amide attacks  $[\text{Ru}(\text{NH}_3)_5\text{NO}]^{3+}$ , forming  $[\text{Ru}(\text{NH}_3)_5(\text{N}_2)]^{2+}$ ,<sup>28</sup> and  $\text{RNH}_2$  ( $\text{R} = p\text{-MeC}_6\text{H}_4$  or  $p\text{-MeOC}_6\text{H}_4$ ) attacks  $[\text{RuCl}(\text{bipy})_2\text{NO}]^{2+}$  forming  $[\text{RuCl}(\text{bipy})_2(\text{N}_2\text{R})]^{2+}$ .<sup>13</sup> Nucleophilic attack of  $\text{NH}_3$  at  $[\text{Ir}(\text{Br})_5\text{NO}]^-$  would give the ion  $[\text{Ir}(\text{Br})_5(\text{N}_2)]^{2-}$ . The rapid decomposition of the  $\text{N}_2$  complex in contrast to the stability of the

$\text{NO}^+$  and  $\text{CO}^{29}$  complexes illustrates the delicate balance of  $\sigma$ - and  $\pi$ -bonding required to stabilize  $\text{N}_2$  complexes.<sup>22</sup>

Hydrazine hydrate also reacted with the ion  $[\text{Ir}(\text{Br})_5\text{NO}]^-$ , rapidly giving  $[\text{Ir}(\text{Br})_3(\text{N}_2\text{H}_4)_3] \cdot 0.5\text{H}_2\text{O}$  (56%) and 0.23 mol  $\text{N}_2$  per mol  $[\text{Ir}(\text{Br})_5\text{NO}]^-$ . Hydrazine has been shown to give co-ordinated  $\text{N}_3^-$ ,<sup>8,11</sup>  $\text{N}_2\text{O}$ ,<sup>11</sup> or  $\text{N}_2$ .<sup>5,11</sup> when it reacts with nitrosyl complexes. It is possible that co-ordinated  $\text{N}_3^-$  or  $\text{N}_2$  is formed in the present reaction, since the product often showed a sharp absorption at  $2057\text{ cm}^{-1}$ , in the region expected for these ligands. However, the course of the reaction is not certain. The complex  $[\text{Ir}(\text{Br})_3(\text{N}_2\text{H}_4)_3] \cdot 0.5\text{H}_2\text{O}$  may be monomeric with unidentate hydrazine or polymeric with bridging hydrazine. It has been suggested these types may be distinguished by their i.r. spectra,  $\bar{\nu}(\text{N-N})$  being  $931\text{--}936\text{ cm}^{-1}$  in the former case and  $948\text{--}980\text{ cm}^{-1}$  in the latter.<sup>30</sup> The band closest to this region in  $[\text{Ir}(\text{Br})_3(\text{N}_2\text{H}_4)_3] \cdot 0.5\text{H}_2\text{O}$  was at  $940\text{ cm}^{-1}$ , which does not allow an assignment of the structure.

All attempts to prepare the ion  $[\text{Ir}(\text{I})_5\text{NO}]^-$  were unsuccessful. Addition of  $\text{NO}_2^-$  to a solution of  $[\text{IrI}_6]^{3-}$  followed by acidification produced colour changes as for the chloro- and bromo-complexes, but no nitrosyl-containing material could be isolated.

#### EXPERIMENTAL

Iridium trichloride was obtained from Johnson, Matthey, and Mallory, Montreal, and used as received. The salts  $\text{K}[\text{Ir}(\text{X})_5\text{NO}]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) were prepared by a considerably modified version of the literature methods.<sup>18,19</sup>

*Potassium Pentahalogenonitrosyliridate*,  $\text{K}[\text{Ir}(\text{X})_5\text{NO}]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ).—To a solution of the salt  $\text{K}_3[\text{IrCl}_6]$  (0.40 g) in the minimum volume of water ( $10\text{ cm}^3$ ) was added  $\text{NaNO}_2$  (0.10 g), and the resulting solution heated with an accompanying change in colour from green to yellow. When the volume had been reduced to *ca.* one half, concentrated  $\text{HCl}$  ( $15\text{ cm}^3$ ) was added. Continued heating produced gas evolution, a darkening of the solution to a deep red colour, and, finally, appearance of a deep red precipitate. The mixture was cooled to  $5^\circ\text{C}$ , the product collected by filtration, and air dried. It was washed with methanol ( $2 \times 3\text{ cm}^3$ ) and diethyl ether ( $2 \times 3\text{ cm}^3$ ) and dried *in vacuo*; the air-dried solid frequently contained water of crystallization, yield 0.20 g (60%) (Found:  $\text{Cl}$ , 40.5. Calc. for  $\text{Cl}_5\text{IrKNO}$ :  $\text{Cl}$ , 40.4%).  $\bar{\nu}(\text{NO})$  (anhydrous material, Nujol mull) at  $2008\text{ cm}^{-1}$ .  $\lambda_{\text{max}}$ , 268 nm ( $\epsilon > 1 \times 10^4\text{ dm}^3\text{ mol}^{-1}\text{ cm}^{-1}$ ). The bromo-complex was similarly prepared in 60% yield (Found:  $\text{Br}$ , 60.2. Calc. for  $\text{Br}_5\text{IrKNO}$ :  $\text{Br}$ , 60.45%).  $\bar{\nu}(\text{NO})$  (Nujol mull) at  $1958\text{ cm}^{-1}$ ; aqueous solution, 0.025 mm  $\text{CaF}_2$  cell,  $1953\text{ cm}^{-1}$ .  $\lambda_{\text{max}}$ , 322 nm ( $\epsilon 1.07 \times 10^4$ ) and 289 nm ( $\epsilon 1.0 \times 10^4\text{ dm}^3\text{ mol}^{-1}\text{ cm}^{-1}$ ).

*Reaction of Pentahalogenonitrosyliridate(1-) with Hydroxide Ion: Tripotassium Pentahalogenonitrosyliridate*,  $\text{K}_3[\text{Ir}(\text{X})_5\text{NO}_2]$  ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ).—To an ice-cold slurry of the salt  $\text{K}[\text{Ir}(\text{Br})_5\text{NO}]$  (0.30 g) in water ( $1\text{ cm}^3$ ) was added one pellet

(0.2 g) of KOH; the KOH and red  $K[\text{Ir}(\text{Br})_5\text{NO}]$  dissolved to give a green solution of  $[\text{Ir}(\text{Br})_5\text{NO}_2]^{3-}$ . Addition of 95% ethanol gave a green precipitate which was collected by filtration, washed with 95% ethanol and diethyl ether, and dried *in vacuo*, yield 0.12 g (62%) (Found: Br, 52.65; N, 1.75. Calc. for  $\text{Br}_5\text{IrK}_3\text{NO}_2$ : Br, 52.9; N, 1.85%). The chloro-complex was obtained in a similar manner from  $K[\text{Ir}(\text{Cl})_5\text{NO}]$ , except that it often precipitated as a hydrate of unknown stoichiometry. The water of crystallization was removed *in vacuo*, yield 78% (Found: Cl, 33.25; N, 2.45. Calc. for  $\text{Cl}_5\text{IrK}_3\text{NO}_2$ : Cl, 33.25; N, 2.65%). The i.r. spectrum of the chloro-complex was in good agreement with the published spectrum,<sup>31</sup> and that of the bromo-complex was similar. The electronic spectrum of  $[\text{Ir}(\text{Cl})_5\text{NO}_2]^{3-}$  showed two bands at 350 ( $\epsilon$   $6.5 \times 10^3$ ) and at 280 nm ( $\epsilon$   $1.3 \times 10^3$   $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$ ) and  $[\text{Ir}(\text{Br})_5\text{NO}_2]^{3-}$  a shoulder at 272 nm ( $\epsilon$   $8 \times 10^4$   $\text{dm}^3 \text{mol}^{-1} \text{cm}^{-1}$ ) on a high-energy tail.

*Aquation of Pentabromonitrosyliridate(3-): Dipotassium Aquatetabromonitrosyliridate*,  $\text{K}_2[\text{IrBr}_4(\text{NO}_2)\text{H}_2\text{O}]$ .—A solution of the salt  $\text{K}_3[\text{Ir}(\text{Br})_5\text{NO}_2]$  (0.30 g) in water (2  $\text{cm}^3$ ) was set aside at 5 °C for 16 h. Addition of 95% ethanol gave a yellow-brown precipitate which was collected by filtration, washed with ethanol and diethyl ether, and dried *in vacuo*, yield 0.20 g (80%) (Found: Br, 49.05; N, 2.05. Calc. for  $\text{H}_2\text{Br}_4\text{IrK}_2\text{NO}_3$ : Br, 48.85; N, 2.15%). The complex was a 1 : 2 electrolyte in aqueous solution. The i.r. spectrum showed bands at 1350s, 1355(sh), 1271s, and 857w  $\text{cm}^{-1}$  assignable to co-ordinated  $\text{NO}_2^-$ , and 3460 and 1610  $\text{cm}^{-1}$  assignable to co-ordinated  $\text{H}_2\text{O}$ .

*Reaction of Pentahalogenonitrosyliridate(1-) with Ammonia: Dipotassium Amminepentahalogenoiridate*,  $\text{K}_2[\text{Ir}(\text{X})_5\text{NH}_3]$  (X = Cl or Br).—The salt  $K[\text{Ir}(\text{Br})_5\text{NO}]$  (0.30 g) was added to aqueous ammonia ( $d$  0.880  $\text{g cm}^{-3}$ ; 3  $\text{cm}^3$ ). A rapid exothermic reaction, accompanied by vigorous gas evolution, gave a green solution which on cooling deposited a green precipitate of  $\text{K}[\text{NH}_4][\text{Ir}(\text{Br})_5\text{NH}_3]$ . This was collected by filtration, washed with methanol and diethyl ether, and air dried (yield 0.18 g, 58%). The chloro-complex was obtained similarly in 48% yield. The bromo-complex was converted to  $\text{K}_2[\text{Ir}(\text{Br})_5\text{NH}_3]$  by air evaporation of an aqueous ethanol solution in the presence of KBr (Found: Br, 57.8; N, 2.15. Calc. for  $\text{H}_3\text{Br}_3\text{IrK}_2\text{N}$ : Br, 58.15; N, 2.05%). The product was a 1 : 2 electrolyte in aqueous solution and showed i.r. absorption bands appropriate to an ammine complex.

*Reaction of Pentabromonitrosyliridate(1-) with Hydroxylamine: Dipotassium Aquapentabromoiridate*,  $\text{K}_2[\text{Ir}(\text{Br})_5\text{H}_2\text{O}]$ .—One pellet (0.2 g) of KOH was added to a solution of  $\text{NH}_2\text{OH}\cdot\text{HCl}$  (0.47 g) in water (2  $\text{cm}^3$ ) and then  $K[\text{Ir}(\text{Br})_5\text{NO}]$  (0.30 g) added in small portions. When all the  $K[\text{Ir}(\text{Br})_5\text{NO}]$  was in solution, and the accompanying gas evolution had ceased, the green product was precipitated by

addition of 95% ethanol (20  $\text{cm}^3$ ). The product was collected by filtration, washed with 95% ethanol and diethyl ether, and dried *in vacuo*, yield 0.24 g (77%) (Found: Br, 58.15. Calc. for  $\text{H}_2\text{Br}_5\text{IrK}_2\text{O}$ : Br, 58.1%). The complex was a 1 : 2 electrolyte in aqueous solution, and had properties similar to those described in the literature.<sup>28</sup> The i.r. spectrum showed bands attributable to co-ordinated  $\text{H}_2\text{O}$ , unaltered by prolonged drying *in vacuo*.

*Reaction of Pentahalogenonitrosyliridate(1-) with Azide Ion*.—To a solution of  $\text{KN}_3$  (0.02 g) in water (1  $\text{cm}^3$ ) was slowly added the salt  $K[\text{Ir}(\text{Br})_5\text{NO}]$  (0.09 g). When the resultant vigorous gas evolution ceased, 95% ethanol was added giving a green precipitate. This was collected by filtration, washed with 95% ethanol and diethyl ether, and air dried (yield 0.08 g, 80%). The chloro-complex was prepared similarly. The chemical and physical properties of the bromo-complex were similar to those of that produced by the hydroxylamine reaction above.

*Reaction of Pentabromonitrosyliridate(1-) with Hydrazine Hydrate: Tribromotrihydrazineiridium Hydrate (2/1)*,  $[\text{IrBr}_3(\text{N}_2\text{H}_4)_3] \cdot 0.5 \text{H}_2\text{O}$ .—Hydrazine hydrate (85%, 1  $\text{cm}^3$ ) was slowly added to a stirred slurry of the salt  $K[\text{Ir}(\text{Br})_5\text{NO}]$  (1.0 g) in cold water (5  $\text{cm}^3$ ). There was an immediate exothermic reaction with gas evolution. The yellow precipitate which formed was collected by filtration, washed with water, ethanol, and diethyl ether, and dried *in vacuo*, yield 0.45 g (56%) (Found: Br, 41.5; H, 2.40; N, 15.85. Calc. for  $\text{H}_{2.6}\text{Br}_6\text{Ir}_2\text{N}_{12}\text{O}$ : Br, 44.6; H, 2.45; N, 15.65%). The complex was insoluble in all common solvents, diamagnetic, and showed i.r. absorption bands assignable to hydrazine and water.

I.r. spectra were measured on a Perkin-Elmer 457 instrument; electronic spectra on a Bausch and Lomb Spectronic 505; magnetic moments by the Gouy method; conductivities on a Beckman conductivity bridge; and hydrogen-ion concentrations on a Beckman Research pH meter. Gas-evolution experiments were carried out by adding the salts  $K[\text{Ir}(\text{X})_5\text{NO}]$  to the appropriate frozen, degassed, reagent solution and, after evacuation, allowing the mixture to warm up on the vacuum line. Gas volumes were determined by a Toepler pump-manometer system, and analysed on a Hitachi-Perkin-Elmer RMU-60 mass spectrometer. Microanalyses were by A. Bernhardt, West Germany.

We thank the National Research Council of Canada and the University of New Brunswick Research Fund for support, Johnson, Matthey, and Mallory, Montreal, for a generous loan of iridium trichloride, and Dr. F. Grein of this Department for the molecular-orbital calculation on  $\text{NO}^+$ .
