# Crystal and Molecular Structures of Potassium Pentachloro- and Penta-bromo-nitrosyliridate Hydrate 

By Frank Bottomley, Department of Chemistry, University of New Brunswick, Fredericton, New Brunswick E3B 5A3, Canada

#### Abstract

The crystal and molecular structures of the title compounds [ Cl (I), Br (II)] have been investigated by use of diffractometer data. The compounds are isomorphous and isostructural, orthorhombic, space group Pnma or $P n 2_{1} a, Z=4$ : (I), $a=22.416(5), b=6.935(1), c=6.069(1) \AA$ : (II), $a=23.272(9), b=7.261(5), c=$ 6.302 (3) $\AA$. The structures were solved by the heavy-atom method and refined by full-matrix methods to $R 0.049$ [(I), 1704 reflections] and 0.096 [(II), 1291 reflections]. The iridium atom is octahedrally co-ordinated by five halide ions and the nitrogen atom of the NO ligand. Both structures show the trans-shortening influence of NO when co-ordinated formally as $\mathrm{NO}^{+}$. For (I) $\mathrm{Ir}-\mathrm{Cl}(\mathrm{eq})$ distances are $2.335(2)$ and $2.342(2)$, and $\mathrm{Ir}-\mathrm{Cl}(\mathrm{ax})$ $2.286(3) \AA$; for (II) the analogous distances are 2.475(3) and 2.485(3), and 2.419(4) $\AA$. Ir N and $\mathrm{N}-\mathrm{O}$ distances and $\operatorname{Ir}-\mathrm{N}-\mathrm{O}$ angles are for (I) $1.76(1)$ and $1.12(2) \AA$, and 174.3(1) ${ }^{\circ}$, and for (II) $1.71(2)$ and 1.17(4) $\AA$, and 170.3(3).

In a previous paper on nitrosyls of ruthenium ammines I indicated interest in the structures of those nitrosyl complexes which are reactive towards nucleophiles. ${ }^{1}$ I wish to correlate the electrophilic behaviour of coordinated NO (co-ordinated formally as $\mathrm{NO}^{+}$) to the structural parameters of its complexes, and to investigate the trans-influence of co-ordinated $\mathrm{NO}^{+}$. The complexes $\mathrm{K}\left[\mathrm{IrCl}_{5} \mathrm{NO}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (I) and $\mathrm{K}\left[\mathrm{IrBr}_{5} \mathrm{NO}\right] \cdot \mathrm{H}_{2} \mathrm{O}$ (II) are very reactive towards nucleophiles, and they have different equilibrium constants for their reaction with $\mathrm{OH}-{ }^{-2}$ They also contain identical axial and equatorial ligands, and therefore have the internal standard necessary for an unambiguous assessment of the trans-influence of $\mathrm{NO}^{+}$. These complexes are therefore ideal for my interests, and their structures are reported here.

## EXPERIMENTAL

Complexes (I) and (II) were prepared by the literature method. ${ }^{2}$ Suitable crystals of (II) were obtained by setting aside a saturated solution of the complex in concentrated hydrobromic acid for several days at $5^{\circ} \mathrm{C}$. Crystals were mounted in thin-walled glass tubes for $X$-ray measurements. Weissenberg photographs ( $\mathrm{Cu}-K_{\alpha}$ radiation) of the $h 0-4 l$ layers showed systematic absences and symmetry in agreement with the orthorhombic space groups Pnma ( $D_{2 h}^{16}$, No. 62) or $P n 2_{1} a$ (non-standard setting of $P n a 2_{1}\left(C_{2 v}^{9}\right.$, No. 33)). The former was used in the structure refinement, though a good case can be made for the latter as the correct space group (vide infra).

Crystal Data.-(II), $\mathrm{Br}_{5} \mathrm{H}_{2} \mathrm{IrKNO}_{2}, M=687.9$, Orthorhombic, $a=23.272(9), b=7.261(5), c=6.302(3) \AA, U=$ $1064.9 \AA^{3} . \quad D_{\mathrm{c}}=4.29, Z=4$. $\mathrm{Mo}-K_{\alpha_{1}}$ radiation, $\lambda=$
${ }^{1}$ F. Bottomley, J.C.S. Dalton, 1974, 1600.
${ }^{2}$ F. Bottomley, S. G. Clarkson, and S. B. Tong, J.C.S. Dalton, 1974, 2344.
$0.70926 \AA ; \mu\left(\mathrm{Mo}-K_{\alpha}\right)=334.6 \mathrm{~cm}^{-1} . \quad D_{\mathrm{c}}$ is reasonable for this type of complex. No liquid with a sufficiently high density could be found to determine $D_{\mathrm{m}}$.
On setting aside a saturated solution of (I) in concentrated hydrochloric acid at $5^{\circ} \mathrm{C}$, well-formed crystals were deposited. However, photographic examination showed these were face-centred cubic and of $m 3 m$ symmetry ( $a=$ 6.98 from uncalibrated photographs). These crystals were not further investigated since it seemed highly probable that they had a disordered structure. Crystals of (I) which were isomorphous with those of (II) were obtained by setting aside a saturated solution of (I) in concentrated hydrochloric acid at $-35^{\circ} \mathrm{C}$ for several weeks.

Crystal Data.-(I), $\mathrm{Cl}_{5} \mathrm{H}_{2} \mathrm{IrKNO}_{2}, \quad M=456.6, \quad a=$ $22.416(5), b=6.935(1), c=6.069(1) \AA, U=943.4 \AA^{3}, D_{\mathrm{c}}=$ $3.21, Z=4$. $\mu\left(\mathrm{Mo}-K_{\alpha}\right)=168.1 \mathrm{~cm}^{-1}$.

Collection and Reduction of Intensity Data.-The crystal of (I) used for the determination of intensities was a needle (ca. $0.16 \times 0.8 \times 0.08 \mathrm{~mm}$ ) and was mounted with the needle axis (b) ca. $8^{\circ}$ mis-set from the $\phi$ axis of a Picker FACS 1 diffractometer. ${ }^{3}$ A needle of (II) ( $0.08 \times 1.0 \times 0.12 \mathrm{~mm}$ ) was similarly mounted. Cell dimensions were determined from 12 accurately centred reflections with $2 \theta>50^{\circ}$ for (I) and $>40^{\circ}$ for (II). For (I) a unique $h k l$ data set was collected to $2065^{\circ}$ ( 1832 reflections) and for (II) to $60^{\circ}$ ( 1679 reflections) by the $\omega-2 \theta$ scan technique. Instrument settings were basically as described previously, ${ }^{4}$ with the exception that the diffractometer is now equipped with a graphite monochromator and that because of severe reflection overlap at high $2 \theta$ (due to the large $a$ cell dimension) the counter aperture was reduced to $c a .0 .5 \mathrm{~cm}$ in width. Three standard reflections, monitored every 50 reflections, showed no significant changes for (I) or (II).

Absorption, Lorentz, and polarisation corrections were
${ }^{3}$ W. H. Zachariasen, Acta Cryst., 1965, 18, 705.
${ }^{4}$ F. Bottomley, J.C.S. Dalton, 1972, 2148.
applied to the data [ $\mu R$ 5.5-25.1 for (I), and 3.5--12.5\% for (II)]. ${ }^{5}$ Reflections with a net count $<10$ or $<0.05$ times background were considered unobserved and not used in the structure refinements. The structure of (I) was solved from 1672 observed structure amplitudes, and 'that of (II) from 1291.

Structure Solution and Refinement.-The structures of (I) and (II) were solved in parallel by use of standard Patterson, isomorphous replacement, and Fourier techniques. The scattering factor curve for $\mathrm{Ir}^{4+}$ was taken from ref. 6 and those for $\mathrm{Br}^{-}, \mathrm{Cl}^{-}, \mathrm{N}$, and O from ref. 7; those for $\mathrm{Ir}^{4+}, \mathrm{Br}^{-}$, and $\mathrm{Cl}^{-}$were corrected for both the real and imaginary parts of the anomalous dispersion. Refinement was by the fullmatrix method, the function minimised being $\Sigma w\left(\left|F_{0}\right|-\right.$ $\left.\left|F_{\mathrm{c}}\right|\right)^{2}$. Weighting schemes of the form $w=1 /\left(a+F_{\mathrm{o}}+\right.$
test has been questioned in cases where there are serious correlation problems. ${ }^{9,10}$ These occur in the $P n 2_{1} a$ refinement, correlation coefficients of up to 0.88 being found between the parameters of the four equatorial chlorine atoms. As a result the $\mathrm{Ir}-\mathrm{Cl}$ bond distances for these four chemically equivalent atoms differed by up to $0.1 \AA$, though the mean was identical to that from the Pnma refinement, and none of the other bond distances or angles were significantly different. An $E$ statistics test favoured the noncentric $P n 2_{1} a$ also, though not strongly. However, because of the correlation problem it was decided to accept the Pnma refinement, recognising that the errors quoted may be too small. ${ }^{10}$ The situation was similar for (II), except that the $E$ statistics test here favoured the centric Pnma, again not strongly. Again, Pnma was accepted.

$B F_{0}{ }^{2}+C F_{0}{ }^{3}$ ), where $A=14, B=3.9 \times 10^{-3}$, and $C=$ $1.9 \times 10^{-5}$ for (I) and $A=28, B=3.3 \times 10^{-3}$, and $C=$ $1.38 \times 10^{-5}$ for (II) were used. With the $\mathrm{Ir}, \mathrm{Cl}$, or Br , and K atoms given anisotropic thermal parameters and N and O isotropic, refinements of both structures in space group Pnma proceeded normally to convergence at $R 0.049$ ( $R^{\prime} 0.080$ ) for (I) and $0.096\left(R^{\prime} 0.10\right)$ for (II), where $R^{\prime}=\left[\Sigma w\left(\left|F_{0}\right|-\right.\right.$ $\left.\left.\left|F_{\mathrm{c}}\right|\right)^{2} / \sum w\left(F_{\mathrm{o}}\right)^{2}\right]^{1 / 2}$. An extinction parameter was included in the last cycles of refinement.

At this stage various tests were made. There was no significant decrease in $R$ or $R^{\prime}$ when the light atoms were allowed to vibrate anisotropically. Refinement of (I) in the non-centric $P n 2_{1} a$ space group gave $R 0.044$ ( $R^{\prime} 0.067$ ). This decrease is significant at $>0.005$ confidence level according to Hamilton's test. ${ }^{8}$ However, the validity of this

[^0]No attempt was made to locate the hydrogen atoms of the water of crystallisation. On the final cycles no shift was $>0.01 \sigma$ for (I) or $>0.02 \sigma$ for (II). Difference-Fourier syntheses showed maxima and minima of 3.5 and -2.7 for (I) and 6.8 and $-4.9 \mathrm{e}^{-3}$ for (II); in both cases negative and positive peaks were $<1 \AA$ from the Ir atom. No other significant peaks were found for either structure. An error analysis showed poor agreement for the 0 kl reflections in both cases, but deletion of these reflections and re-refinement gave no change in $R$ or $R^{\prime}$, nor were the parameters significantly affected. The estimated standard deviation of an observation of unit weight was 0.41 electrons for ( I ) and 0.85 for (II). Tables 1 and 2 give the parameters and standard deviations from the last cycle for (I) and (II) respectively (the numbering scheme is shown in the Figure).

[^1]Observed and calculated structure factors are listed in Supplementary Publication No. SUP 21505 (28 pp., 1 microfiche).*

Numbering scheme for the $\left[I \mathrm{X}_{5} \mathrm{NO}\right]^{-}$anion $(\mathrm{X}=\mathrm{Cl}$ or Br$)$

## DISCUSSION

The structures consist of well separated $\mathrm{K}^{+}$cations, $\left[\operatorname{IrX}_{5} \mathrm{NO}^{-}\right.$anions, and water of crystallisation. The shortest cation-anion distance in (I) is $3.34 \AA[\mathrm{~K} \cdots \mathrm{Cl}(\mathrm{I})]$ and the shortest distance involving the water oxygen is $3.47 \AA[\mathrm{O}(2) \cdots \mathrm{Cl}(1)]$. For (II) these same distances are $3.51[\mathrm{~K} \cdots \mathrm{Br}(\mathrm{l})]$ and $3.65 \AA[\mathrm{O}(2) \cdots \mathrm{Br}(\mathrm{l})]$. The nitrosyl oxygen atom $[\mathrm{O}(1)]$ is $3.24 \AA$ from the trans -Cl $[\mathrm{Cl}(3)]$ of an adjacent anion in (I) and $3.37 \AA$ from $\mathrm{Br}(3)$ in (II). Hence hydrogen bonding must be weak and distortions of the anions due to non-bonded interactions very small. Inspection of the distances (uncorrected) and angles (Table 3) and a selection of weighted

mean planes (Table 4) for (I) shows distortions of the anion from idealised $C_{4 v}$ symmetry are small [strict $C_{8}$ symmetry is crystallographically imposed by a plane through $\mathrm{Cl}(3)$, $\mathrm{Ir}, \mathrm{N}$, and $\mathrm{O}(1)$, bisecting $\mathrm{Cl}(1) \cdots \cdot \mathrm{Cl}\left(\mathbf{1}^{\prime}\right)$ and $\mathrm{Cl}(2) \cdots \mathrm{Cl}\left(2^{\prime}\right)$ (see Figure)]. The distortions are mainly in the $\mathrm{Ir}-\mathrm{N}-\mathrm{O}$ and $\mathrm{Cl}(3)-\mathrm{Ir}-\mathrm{N}$ angles. Tables 5 and 6 give the same information for (II), and the same, but rather larger, deviations from $C_{4 v}$ symmetry are observed. In both cases the equatorial halides are bent away from $\mathrm{NO}^{+}[0.08 \AA$ in (I) and $0.09 \AA$ in (II)].

The mean $\mathrm{Ir}-\mathrm{Cl}(\mathrm{eq})$ distance in the anion of ( I ) is
$2.338_{5}(2)$ and the $\mathrm{Ir}-\mathrm{Cl}(\mathrm{ax})$ distance 2.286(3) $\AA$. This confirms the suggestion, originally made by Veal and Hodgson, ${ }^{11}$ from a study of $\left[\mathrm{RuCl}_{5} \mathrm{NO}\right]^{2-}$, that when the good $\pi$-acceptor but poor $\sigma$-donor ligand $\mathrm{NO}^{+}$is trans to a good $\sigma$-donor ligand such as $\mathrm{Cl}^{-}$a short $\mathrm{M}-\mathrm{X}$ bond

* See footnote to Table 4.
trans to $\mathrm{NO}^{+}$will result. Previous attempts to confirm this idea unambiguously have been only partially successful, ${ }^{1}$ but the $0.05 \AA$ difference observed here is even more marked than the $0.02 \AA$ difference for $\left[\mathrm{RuCl}_{5} \mathrm{NO}\right]^{2-} .{ }^{11}$ The ability of $\mathrm{NO}^{+}$to withdraw electrons from iridium by $\pi$-bonding and hence to shorten the other ligand distances is further illustrated when the present $\mathrm{Ir}-\mathrm{Cl}$ distances are compared with previously found distances. For a wide variety of six-co-ordinate, formally $\mathrm{Ir}^{\text {II }}$, complexes (many containing $\pi$-acceptor groups such as CO or $\mathrm{R}_{3} \mathrm{P}$ ) the $\mathrm{Ir}-\mathrm{Cl}$ distances are in the range $2.35-$

[^2]$2.52 \AA \AA^{12-21}$ The complex most nearly comparable to (I) is $\mathrm{K}\left[\operatorname{IrCl}_{5}\left(\mathrm{C}_{4} \mathrm{H}_{4} \mathrm{~N}_{2}\right)\right] \cdot 1 / 2 \mathrm{H}_{2} \mathrm{O}$, for which the mean $\mathrm{Ir}-\mathrm{Cl}(\mathrm{eq})$ distance is $2.351(3)$ and $\mathrm{Ir}-\mathrm{Cl}(\mathrm{ax}) 2.379(2) \AA .^{12}$ The $\mathrm{Ir}-\mathrm{Cl}(\mathrm{ax})$ distance in (I) $[2.286(3) \AA]$ is the shortest $\mathrm{Ir}{ }^{\text {III }}-\mathrm{Cl}$ distance yet observed, and is in fact $0.03 \AA$ shorter than the $\mathrm{Ir}^{\mathrm{IV}-\mathrm{Cl}}$ distance $[2.324(5) \AA]$ in $\left[\mathrm{IrCl}_{4}{ }^{-}\right.$ $\left.\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{2}\right] \cdot{ }^{18}$ Structures containing $\mathrm{Ir}-\mathrm{Br}$ bonds are too scarce to reinforce the argument by comparison with the structure of (II), but the $0.06 \AA$ difference between the mean $\operatorname{Ir}-\mathrm{Br}(\mathrm{eq})[2.480(3) \AA]$ and $\mathrm{Ir}-\mathrm{Br}(\mathrm{ax})[2.419(4) \AA]$ distances provides further confirmation of the transshortening influence of co-ordinated $\mathrm{NO}^{+}$.

There does not appear to be any previous structural information on six-co-ordinate iridium(III) nitrosyls. The $\mathrm{Ir}-\mathrm{N}$ and $\mathrm{N}-\mathrm{O}$ distances, and $\mathrm{Ir}-\mathrm{N}-\mathrm{O}$ angles for (I) and (II), are in the same ranges as observed for other complexes ${ }^{22-28}$ containing the IrNO moiety when this is approximately linear. The short NO distance in (I) may reflect its extremely high stretching frequency $\left(2008 \mathrm{~cm}^{-1}\right)$. The $\mathrm{Ir}-\mathrm{N}$ and $\mathrm{N}-\mathrm{O}$ distances in (I) and

(II) follow the trend expected from their $v(\mathrm{NO})$ values, i.e. back donation via $\pi$-bonding is greater in (II) than (I), resulting in a shorter $\mathrm{M}-\mathrm{N}$ and longer $\mathrm{N}-\mathrm{O}$ distance. However, the errors are such, particularly for (II) (where the absorption coefficient is so high that any minor imperfections of the crystal or errors in determining its dimensions will produce large errors in the structure amplitudes) that the differences are only marginally significant. The $\mathrm{Ir}-\mathrm{N}-\mathrm{O}$ angles are reasonable close to $180^{\circ}$, and because of the errors the deviations from linearity (which should not be found for complexes of strict $C_{4 v}$ symmetry ${ }^{29,30}$ ) are again only marginally significant.

I thank Dr. H. Lynton for the use of the $X$-ray facilities, Dr. P. White for helpful discussions and assistance with computor programmes, Dr. S. G. Clarkson for samples of (I) and (II), Johnson, Matthey for a generous loan of iridium, and the National Research Council of Canada for financial support.
