Alkyl-exchange Reactions and their Catalysis in Platinum(1) Complexes

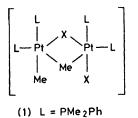

By Richard J. Puddephatt * and Peter J. Thompson, Donnan Laboratories, The University of Liverpool, Liverpool L69 3BX

A study of the symmetrisation reactions of $[PtR_2L_2]$ with $[PtX_2L_2]$ to give $[PtXRL_2]$ has been made (R = Me, Ph, or C \equiv CMe; L = PEt₃, PMe₃, PMe₂Ph, or AsMe₃; X = Cl, I, NCS, NO₂, or NO₃). The dependence of the reaction rate and stereochemistry on the substituents R, X, and L has been studied and the reaction mechanism is discussed. The reaction of *cis*- $[PtCl_2(PMe_2Ph)_2]$ with *cis*- $[PtMe_2(PMe_2Ph)_2]$ to give *cis*- $[PtClMe(PMe_2Ph)_2]$ is catalysed by $[Pt_2Cl_4(PMe_2Ph)_2]$, but the catalyst is destroyed in a competing reaction with *cis*- $[PtMe_2(PMe_2Ph)_2]$ to give *cis*- $[PtMe_2(PMe_2Ph)_2]$.

RECENT research indicates that alkyl transfer between transition-metal centres [equation (1); M,M' = metal, R = alkyl, X = halogen] occurs readily in many cases ¹⁻³ and that some unexpected reaction products can be rationalised on this basis. Examples include the reactions of [AuMe(PMe₃)] with methyl iodide ⁴ or trifluoromethyl iodide ⁵ and of *cis*-[PtMe₂(PMe₂Ph)₂] with nitrogen monoxide.⁶ In some cases the reactions are sufficiently rapid that they might be expected to occur in catalytic sytems where transition-metal alkyls are implicated as intermediates.

$$M^{-}R + M'^{-}X \longrightarrow M^{-}X + M'^{-}R$$
(1)

Some methyl-for-halogen exchange reactions between platinum(II), palladium(II), gold(I), and gold(III) complexes have been reported previously, and an $S_{\rm E}2$ (cyclic) mechanism was proposed.^{1,2} The evidence was: (*i*) many of the reactions followed second-order kinetics; (*ii*) the reactivity could be correlated with the lability of both the metal alkyl and metal halide toward substitution reactions; and (*iii*) the reaction of *cis*-[PtMe₂(PMe₂Ph)₂]

with cis-[PtX₂(PMe₂Ph)₂] took place with retention of stereochemistry at both platinum centres to give cis-[PtXMe(PMe₂Ph)₂] as the product of kinetic control when X = Cl or NO₃. An intermediate or transition state of structure (1) was invoked.

The general symmetrisation reaction of equation (2) has now been studied in more detail, and in this paper the

$$PtR_{2}L_{2}] + [PtX_{2}L_{2}] \longrightarrow [PtXRL_{2}]$$
(2)

Also reported is a remarkable catalysis of some sym metrisation reactions by the complex $[Pt_2Cl_4(PMe_2Ph)_2]$. A preliminary account of some of this work has been published.⁷

RESULTS AND DISCUSSION

cis-[PtMe₂(PMe₂Ph)₂] with cis-[Pt(NCS)₂(PMe₂Ph)₂] and cis-[Pt(NO₂)₂(PMe₂Ph)₂].—The reactions of cis-[PtMe₂(PMe₂Ph)₂] with cis-[Pt(NCS)₂(PMe₂Ph)₂] and cis- $[Pt(NO_2)_2(PMe_2Ph)_2]$ were monitored by recording the n.m.r. spectra of reaction mixtures periodically. The aim was to study effects on the binding position of the ambidentate thiocyanato- and nitro-ligands during the exchange reaction. Both are N-bonded in cis-[PtX₂- $(PMe_2Ph)_2$ derivatives. If the cyclic intermediate of the exchange reaction involves Pt-NCS-Pt or Pt-N(0)O-Pt bridges, then one might expect the product to contain equimolar amounts of trans-[Pt(NCS)Me(PMe₂Ph)₂] and $trans-[Pt(SCN)Me(PMe_2Ph)_2]$ or trans-[Pt(NO₂)Me-(PMe₂Ph)₂] and trans-[Pt(ONO)Me(PMe₂Ph)₂] respectively. The reactions took place readily, being complete in 1 h at 33 °C with cis-[Pt(NO₂)₂(PMe₂Ph)₂] and 4 d at 33 °C with cis-[Pt(NCS)₂(PMe₂Ph)₂]. However, the products were trans- $[Pt(NO_2)Me(PMe_2Ph)_2]$, with Nnitro-groups only, and an equilibrium mixture of trans-[Pt(NCS)Me(PMe₂Ph)₂] (80%) and trans-[Pt(SCN)Me-(PMe₂Ph)₂] (20%) respectively. In the latter case the same ratio of isomers was obtained by methylation of $cis-[Pt(NCS)_2(PMe_2Ph)_2]$ by $[AuMe(PMe_2Ph)]$. It seems that isomerisation between the linkage isomers is faster than the exchange reactions, so that no evidence for or against nitro- or thiocyanato-bridge formation in the reaction was obtained. Combined with earlier work 1,2,8 the rate of reaction of cis-[PtMe₂(PMe₂Ph)₂] with cis-

cis-[PtCl₂L₂] with cis-[PtMe₂L₂'].—The symmetrisation reactions of cis-[PtCl₂L₂] with cis-[PtMe₂L₂] to give [PtClMeL₂] were studied for different tertiary phosphine ligands, L. The final product in each case was trans-[PtClMeL₂] although the *cis* isomer could be identified at intermediate stages when $L = PMe_2Ph$, and in methanol but not in dichloromethane solution, when $L = PEt_3$, thus confirming the observations of Visser et al.³ Little significance can be attached to the apparent solvent dependence since it is possible that the *cis* isomer is formed in the exchange reaction in each case but that the isomerisation to trans-[PtClMe(PEt₃)₂] is faster in dichloromethane than in methanol. The rates followed the order $L = PEt_3$ $(t_1 \ ca. \ 1 \ h) \gg PMe_3$ $(ca. \ 2 \ d) \gg$ PMe₂Ph (ca. 15 d at 34 °C). Previous studies have established that similar exchange reactions take place as fast or faster for PMe₂Ph than for PMePh₂ complexes of Pt^{II}.1

Reaction of cis-[PtMe₂(PEt₃)₂] with cis-[PtCl₂-(PMe₂Ph)₂] gave initially a 1:1 mixture of *trans*-[PtClMe(PEt₃)₂] and *trans*-[PtClMe(PMe₂Ph)₂], this reaction being half-complete in *ca*. 8 h at 20 °C. A much slower phosphine-exchange process then took place to give a mixture of the initial products and *trans*-[PtClMe(PEt₃)-(PMe₂Ph)] in the proportion *ca*. 1:1:2 as expected from statistical considerations only. This reaction was halfcomplete in *ca*. 10 d at 20 °C. The final product was characterised by the methylplatinum resonance in the ¹H n.m.r. spectrum which appeared as a doublet of doublets due to coupling with two non-equivalent phosphorus atoms.

In contrast, cis-[PtMe₂(PMe₂Ph)₂] and cis-[PtCl₂-(PEt₃)₂] gave no detectable reaction after 1 week at 20 °C. Reaction is thermodynamically favourable since, in the presence of [Pt₂Cl₄(PMe₂Ph)₂] as catalyst (see later), cis-[PtClMe(PMe₂Ph)₂] and trans-[PtClMe(PEt₃)₂] are formed. If a cyclic transition state is involved then steric interactions should be very similar in the intermediates (2) and (3) formed from cis-[PtMe₂(PMe₂Ph)₂] and cis-[PtCl₂(PEt₃)₂] and from cis-[PtMe₂(PEt₃)₂] and cis-[PtCl₂(PMe₂Ph)₂], so that the different rates of reaction must be attributed to electronic effects. The results are mostly readily explained if the basicity of the phosphine ligand L in cis-[PtMe₂L₂] is the most important factor in determining the reactivity. In view of this strong dependence of the rate on the nature of the

phosphine ligands, and of the catalysis of the exchange reactions by the phosphine scavenger [Pt₂Cl₄(PMe₂Ph)₂] (see later), it might be argued that the rate-determining step in the exchange reactions involves dissociation of a tertiary phosphine ligand from cis-[PtMe₂L₂] to give the three-co-ordinate [PtMe₂L] which then rapidly reacts with cis-[PtCl₂L₂]. If this were the case, the exchange reactions would be expected to take place faster with complexes of tertiary arsine ligands since the ligand dissociation would then occur more readily.9,10 The reaction when $L = AsMe_3$ followed overall second-order kinetics (using equal concentrations of starting materials) with a rate constant of $2.8 imes 10^{-5} ext{ dm}^3 ext{ mol}^{-1} ext{ s}^{-1}$ at 34 °C in dichloromethane solution. Under the conditions used the half-life was ca. 3 d when $L = AsMe_3$ compared with ca. 2 d for $L = PMe_3$ under similar conditions. Thus the dissociative mechanism is considered unlikely on this basis, and also since a mechanism involving slow ligand dissociation should give rise to a kinetic form which is first order in the complex from which the ligand is lost and zero'th order in the other complex. Thus the

observation of overall second-order kinetics is not consistent with this mechanism.

[PtI₂(PMe₂Ph)₂] with [PtR₂(PMe₂Ph)₂].—It is interesting to compare the relative rates of reaction of [PtI₂-(PMe₂Ph)₂] with cis-[PtMe₂(PMe₂Ph)₂] and with trans-[PtPh₂(PMe₂Ph)₂] to give trans-[PtIMe(PMe₂Ph)₂] and trans-[PtIPh(PMe₂Ph)₂] respectively. The former reaction was complete in 1 d at 20 °C in dichloromethane solution, but the latter reaction required 2 weeks at 60 °C to reach completion. The complex trans-[Pt(C=CMe)2- $(PMe_2Ph)_2$ did not react with $[PtI_2(PMe_2Ph)_2]$ at 60 °C over a period of several weeks. The relatively low reactivity of the phenylplatinum complex is perhaps surprising since electrophilic attack is expected to take place more readily with aromatic than with aliphatic derivatives. For example, the symmetrisation reaction of HgI₂ with HgPh₂ is very much faster than with HgMe₂,¹¹ and reactions of SnMe₃Ph with electrophiles invariably lead to cleavage of the phenyltin rather than a methyltin bond.¹² Various interpretations can be made for this difference. Thus steric hindrance to formation of the five-co-ordinate transition state could be greater in the phenylplatinum compared with the methylplatinum

¹¹ R. E. Dessy and I. K. Lee, J. Amer. Chem. Soc., 1961, 82, 689.

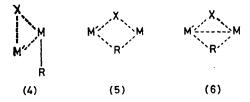

¹² R. C. Poller, 'The Chemistry of Organotin Compounds,' Logos, London, 1970.

complexes. Steric effects would be expected to be much greater than in the linear mercury(II) derivatives. There also appears to be a larger difference between the phenyland methyl-metal bond energies for platinum than for mercury derivatives. Thus M-C bond energies are 250 kJ mol⁻¹ for trans-[PtPh₂(PEt₃)₂],¹³ 144 kJ mol⁻¹ for fac-[PtIMe₃(PMe₂Ph)₂],¹⁰ 136 kJ mol⁻¹ for HgPh₂, and 122 kJ mol⁻¹ for HgMe₂.¹⁴ The high Pt-Ph bond energy may thus be partially responsible for the low reactivity of the phenylplatinum complex. The dependence of the rate of reaction on the nature of R and L in $[PtR_2L_2]$

$$\begin{array}{ccc} M-X + M'-R &\longrightarrow M'-X + M-R & (3) \\ & & & \\ & & M \end{array}$$

gives $R = Me > Ph > C \equiv CMe$ and $L = PEt_3 > PMe_3$ $> PMe_{2}Ph > PMePh_{2}$. This is also the order of expected electron-donor ability of the groups R and L, and the order would be expected if the exchange reactions took place by an oxidative-addition-reductive-elimination mechanism [equation (3)].

The mechanism merits consideration since cleavage of the phenylplatinum bond in trans-[PtPh₂(PEt₃)₂] by HCl has been shown to take place via a hydridoplatinum-(IV) intermediate,¹⁵ and oxidative addition of a platinumhalogen bond to the platinum(0) complex $[Pt(PPh_3)_4]$ has been reported.¹⁶ This mechanism cannot be expected to operate in cleavage of methylgold bonds in [AuMe₃(PMe₃)] since Au^{III} cannot readily undergo oxidative-addition reactions, but could play a part in reactions of gold(I) or platinum(II) alkyls where oxidation occurs readily. The transition states for the oxidativeaddition and $S_{\rm E}2$ (cyclic) mechanisms may be represented

as (4) and (5) respectively. These are not dissimilar and an attractive hypothesis is that intermediate mechanisms between these extremes are possible involving some metal-metal bond formation as shown in structure (6). Whether the transition state resembled (4) or (5) most closely would then depend on the reactivity of the metal alkyl, MR, towards oxidative addition.

Methylation of [Pt₂Cl₂(µ-Cl)₂(PMe₂Ph)₂].—cis-[PtMe₂- $(PMe_2Ph)_2$ and $[Pt_2Cl_2(\mu-Cl)_2(PMe_2Ph)_2]$ (probably trans) reacted rapidly according to equation (4), the reaction being complete within 5 min at room temperature. The dimeric complex cis-[Pt₂(μ -Cl)₂Me₂(PMe₂Ph)₂]

* Throughout this paper: $1 \text{ D} \approx 3.33 \times 10^{-30} \text{ Cm}$.

¹³ S. J. Ashcroft and C. T. Mortimer, J. Chem. Soc. (A), 1967, 930. 14

could not be isolated from this reaction mixture in pure form, but was prepared independently by methylation of $[Pt_{o}Cl_{o}(\mu-Cl)_{o}(PMe_{o}Ph)_{o}]$ with tetramethyltin. In this case the product was easily separated from excess of SnMe₄ and from the trimethyltin chloride formed in the reaction. Consistent with the proposed formulation is the ¹³C n.m.r. spectrum which contains two resonances due to the PCH₃ and PtCH₃ groups, each appearing as a 1:1 doublet due to coupling with the adjacent ³¹P and

$$2 \operatorname{cis-[PtMe_2(PMe_2Ph)_2]} + [Pt_2Cl_2(\mu-Cl)_2(PMe_2Ph)_2] \longrightarrow 2 \operatorname{trans-[PtClMe(PMe_2Ph)_2]} + \operatorname{cis-[Pt_2(\mu-Cl)_2Me_2(PMe_2Ph)_2]} (4)$$

with satellites of 0.25 intensity due to coupling with ¹⁹⁵Pt. The ¹H n.m.r. spectrum also contained a 1:1 doublet due to the PCH₃ groups, but the PtCH₃ resonance appeared as a broad triplet at 35 °C and as a doublet of doublets at low temperature. Again satellites due to coupling with ¹⁹⁵Pt of intensity 0.25 were observed. The low-temperature spectrum is surprising since in similar complexes cis-[Pt₂Me₂(μ -SMe)₂(PMe₂Ph)₂] the methylplatinum resonance appears as a 1 : 1 doublet due to coupling with the adjacent phosphorus atom only,¹⁷ and in the ¹³C n.m.r. spectra no coupling of the PtCH₃ carbon atom to the distant ³¹P nucleus is observed in either $cis-[Pt_2(\mu-Cl)_2Me_2(PMe_2Ph)_2]$ or $cis-[Pt_2Me_2 (\mu$ -SMe)₂(PMe₂Ph)₂]. The further splitting of the PtCH₃ resonance in the ¹H n.m.r. spectrum, presumably due to coupling with the remote ³¹P, is therefore anomalous. {The ³¹P nuclei and PtCH₃ protons should actually give a second-order [AX₃]₂ splitting pattern, the form of which depends on the magnitude of ${}^{4}J(PP)$ relative to ${}^{3}J(PH)$ + $^{5}J(PH)$.} The *cis* configuration is deduced from the dipole moment of 4.4 ± 0.2 D in toluene solution.* This is very similar to the value for cis-[Pt₂(μ -Br)₂Ph₂(PPr₃)₂] of 4.05 D.¹⁸ The complex reacted immediately with 2 mol equiv. of dimethylphenylphosphine to give a mixture of cis- and trans-[PtClMe(PMe₂Ph)₂] in the ratio ca. 2:3, followed by slower isomerisation of the *cis* to the more stable trans isomer.

Catalysis of Exchange Reactions by $[Pt_2Cl_2(\mu-Cl)_2-$ (PMe₂Ph)₂].—The symmetrisation reaction between cis-[PtMe₂(PMe₂Ph)₂] and cis-[PtCl₂(PMe₂Ph)₂] was catalysed by $[Pt_2Cl_2(\mu-Cl)_2(PMe_2Ph)_2]$. The nature of the catalysis is illustrated in Figures 1 and 2, and the chief results are summarised briefly.

(1) In general, a rapid catalytic effect was observed followed by a plateau region in which the reaction proceeded slowly as in the uncatalysed process. The extent of conversion in the rapid catalytic process was approximately proportional to the catalyst concentration up to a catalyst concentration of 2 mol% (at which >70% con-

version took place) but then tailed off at higher catalyst concentrations (Figure 2). Addition of more catalyst to a system in which reaction was incomplete caused a further rapid reaction to occur.

(2) The product of reaction was cis-[PtClMe(PMe₂Ph)₂] which is thermodynamically less stable than the *trans* isomer.

(3) In order to observe the catalytic effect it was necessary to add the catalyst to cis-[PtCl₂(PMe₂Ph)₂] followed by addition of cis-[PtMe₂(PMe₂Ph)₂]. If the catalyst was added to cis-[PtMe₂(PMe₂Ph)₂], reaction to give cis-[Pt₂(μ -Cl)₂Me₂(PMe₂Ph)₂] occurred and no catalytic effect was observed. The complex cis-[Pt₂(μ -Cl)₂Me₂-(PMe₂Ph)₂] did not catalyse the symmetrisation reaction and did not react with cis-[PtCl₂(PMe₂Ph)₂].

(4) The catalysed reaction of cis-[PtMe₂(PMe₂Ph)₂] with cis-[PtCl₂(PEt₃)₂] took place without scrambling of the phosphine groups.

We have considered two mechanisms for this catalytic effect. In the first mechanism the catalyst could act by abstracting a phosphine ligand from cis-[PtMe₂-(PMe₂Ph)₂] to give three-co-ordinate [PtMe₂(PMe₂Ph)] which is the active methylating agent. Precedents for [Pt₂Cl₄L₂] acting as phosphine scavengers are known.¹⁰ However, a T-shaped three-co-ordinate species would not be stereochemically rigid and would be expected to give at least some *trans*-[PtClMe(PMe₂Ph)₂] after exchange and recombination with phosphine. Also scrambling of

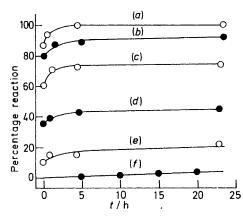

FIGURE 1 Percentage of cis-[PtMe₂(PMe₂Ph)₂] reacted in the catalysed reaction with cis-[PtCl₂(PMe₂Ph)₂] against time. Initial concentration of cis-[PtMe₂(PMe₂Ph)₂] and of cis-[PtCl₂(PMe₂Ph)₂] was 0.116 4 mol dm⁻³. Concentration of catalyst [Pt₂Cl₄(PMe₂Ph)₂]: (a) 1.01×10^{-2} , (b) 8.08×10^{-3} , (c) 2.12×10^{-3} , (d) 1.21×10^{-3} , (e) 4.04×10^{-4} mol dm⁻³, and (f) no catalyst

phosphine groups during the exchange process would be expected but was not observed.

In the second mechanism the catalyst is methylated by cis-[PtMe₂(PMe₂Ph)₂] and then, in turn, methylates cis-[PtCl₂(PMe₂Ph)₂] with regeneration of the catalyst. This mechanism is consistent with all the available data. However, the nature of the reactive intermediate is not known. It is clear that it is not cis-[Pt₂(μ -Cl)₂Me₂-(PMe₂Ph)₂] since this does not catalyse the reaction. Indeed it is formation of this species by reaction (4) which destroys the catalyst. We think it likely that a reactive species with a bridging methyl group, $[Pt_2Cl_2-(\mu-Cl)(\mu-Me)(PMe_2Ph)_2]$, or possibly monomeric $[PtClMe-(PMe_2Ph)]$, is the active intermediate, but further kinetic studies, which are not possible by the n.m.r. technique, are needed to settle this point.

In view of this remarkable catalytic effect it is obviously

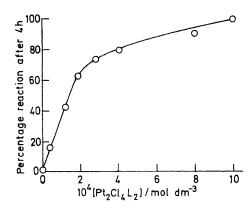

FIGURE 2 Percentage of cis-[PtMe₂(PMe₂Ph)₂] reacted after 4 h in the reaction with cis-[PtCl₂(PMe₂Ph)₂] against the concentration of catalyst

necessary to check very carefully the purity of complexes $[PtCl_2L_2]$ used in studies of methyl-exchange reactions, since a trace amount of $[Pt_2Cl_4L_2]$ impurity could obviously greatly affect the reaction rate.

EXPERIMENTAL

Preparations of starting materials were by literature methods unless given below. Methyl-exchange reactions were carried out in dichloromethane solution (*ca.* 0.1 mol dm⁻³ in each reagent) and were monitored by n.m.r. as described previously.¹ Dipole moments were measured in toluene solvent.

cis-[Pt(NO₃)₂(PMe₂Ph)₂].—To a solution of cis-[PtCl₂-(PMe₂Ph)₂] (0.31 g, 0.58 mmol) in dichloromethane (4 cm³) was added Ag[NO₃] (0.195 g, 1.15 mmol) dissolved in hot methanol (8 cm³). The mixture was stirred for 2 h then filtered to remove AgCl and the solvent was evaporated to give the *product* as white crystals, which were recrystallised from methanol, yield 0.22 g, m.p. 200—203 °C; n.m.r. in CH₂Cl₂ δ (PCH₃) 1.56 (d) [²J(PH) + ⁴J(PH) 11.6, ³J(PtH) 36.4 Hz] (Found: C, 32.2; H, 4.7; N, 4.7. Calc. for C₁₆H₂₂N₂O₆Pt: C, 32.3; H, 3.7; N, 4.7%).

trans-[Pt(C=CMe)₂(PMe₂Ph)₂].—The complex cis-[PtCl₂(PMe₂Ph)₂] (1.0 g, 1.9 mmol) was added to a solution of Li(CCMe) [from LiMe (13 mmol) and excess of propyne in diethyl ether (100 cm³)] cooled to -78 °C. The mixture was allowed to warm to room temperature and was stirred for 2 h. The mixture was hydrolysed and the *product* was obtained by evaporation of the dried ether layer. It was purified by chromatography through a column of silica eluting with dichloromethane, yield 0.6 g, m.p. 173 °C, n.m.r. in CH₂Cl₂ δ (PCH₃) 2.01 (t) [²J(PH) + ⁴J(PH) 6.8, ³J(PtH) 31 Hz], δ (CCH₃) 1.83 (t) [⁵J(PH) 4.2 Hz], i.r. ν (C=C) at 2 116 cm⁻¹ (Found: C, 47.6; H, 4.85. Calc. for C₂₂H₂₈P₂Pt: C, 48.1; H, 5.1%).

 $cis-[PtMe_2(PMe_2Ph)_2]$ with $cis-[Pt(NCS)_2(PMe_2Ph)_2]$.

The complexes cis-[PtMe₂(PMe₂Ph)₂] (0.05 g, 0.1 mmol) and cis-[Pt(NCS)₂(PMe₂Ph)₂] (0.06 g, 0.1 mmol) were mixed in dichloromethane (0.7 cm³) in an n.m.r. tube. The products, identified by the n.m.r. spectra after 4 d at 20 °C, were: trans-[Pt(NCS)Me(PMe₂Ph)₂] (0.16 mmol), n.m.r. δ (PtMe) 0.04 (t) [³J(PH) 7.2, ²J(PtH) 78.5 Hz], δ (PMe) 1.74 (t) [²J(PH) + ⁴J(PH) 6.9, ³J(PtH) 30.3 Hz], i.r. v(CN) at 2 092vs, v(CS) at 820m and 816m cm⁻¹; and trans-[Pt(SCN)Me(PMe₂Ph)₂] (0.04 mmol), n.m.r. δ (PtMe) 0.21 (t) [³J(PH) 7.1, ²J(PtH) 75.0 Hz], δ (PMe) 1.81 (t) [²J(PH) + ⁴J(PH) 6.8, ³J(PtH) 29.5 Hz], i.r. v(CN) at 2 10m cm⁻¹. The mixture of isomers had m.p. 104—105 °C (Found: C, 38.9; H, 4.4; N, 2.4. Calc. for C₁₈H₂₅-NP₂PtS: C, 39.7; H,4.6; N, 2.6%).

cis-[PtMe₂(PEt₃)₂] with cis-[PtCl₂(PMe₂Ph)₂].—Reaction carried out as above gave, after 1 d at 33 °C, trans-[PtClMe-(PEt₃)₂] and trans-[PtClMe(PMe₂Ph)₂] identified by the n.m.r. spectra. After 7 d the major product was [PtCl²Me^c-(PMe₂Ph)^b(PEt₃)^d]; n.m.r. in CH₂Cl₂ δ (PtMe) 0.24 (d, d) [³J(PH) 6.2, 7.0, ²J(PtH) 84.6 Hz].

trans-[PtPh₂(PMe₂Ph)₂] with [PtI₂(PMe₂Ph)₂].—A solution of trans-[PtPh₂(PMe₂Ph)₂] (0.06 g, 0.1 mmol) and [PtI₂(PMe₂Ph)₂] (0.07 g, 0.1 mmol) in dichloromethane (0.9 cm³) was placed in an n.m.r. tube and the tube was sealed *in vacuo*. After 14 d at 60 °C reaction to give *trans*-[PtIPh(PMe₂Ph)₂] was complete, and the product was isolated by evaporation of the solvent, m.p. 111—116 °C,

n.m.r. in CH₂Cl₂ δ (PMe) 1.14 (t) $\lfloor {}^{2}J(PH) + {}^{4}J(PH)$ 7.0, ${}^{3}J(PtH)$ 32.1 Hz] (Found: C, 39.3; H, 4.0. Calc. for C₂₂H₂₇IP₂Pt: C, 39.1; H, 4.0%).

cis-[Pt₂(μ -Cl)₂Me₂(PMe₂Ph)₂].—Excess of SnMe₄ (0.4 g, 2.7 mmol) was added to a solution of [Pt₂Cl₄(PMe₂Ph)₂] (0.4 g, 0.5 mmol) in dichloromethane (10 cm³). After 24 h at room temperature the solvent was evaporated, the *product* was washed with diethyl ether, and recrystallised from dichloromethane-light petroleum to give brown crystals (0.13 g), m.p. 132—135 °C. N.m.r. spectra: ¹H in CH₂Cl₂ at 25 °C, δ (PtMe) 0.39 (t) [J(PH) 6.0, ²J(PtH) 81.6 Hz], δ (PMe) 1.64 (d) [²J(PH) 11.4, ³J(PtH) 51 Hz], at -25 °C δ (PtMe) 0.36 (d, d) [J(PH) 3.6, 4.2, J(PtH) 84 Hz]; ¹³C in CDCl₃, δ (PtCH₃) -13.65 (d) [²J(PC) 30, ¹J(PtC) 708 Hz], δ (PCH₃) 13.47 (d) [¹J(PC) 44, ²J(PtC) 52.4 Hz] (Found: C, 28.5; H, 3.8. Calc. for C₁₈H₂₈Cl₂P₂Pt₂: C, 28.2; H, 3.65%).

Catalysis by $[Pt_2Cl_4(PMe_2Ph)_2]$.—The required volume of a standard solution of $[Pt_2Cl_4(PMe_2Ph)_2]$ (0.024 mol dm⁻³ in dichloromethane) was added to *cis*- $[PtCl_2(PMe_2Ph)_2]$ (0.038 g, 0.07 mmol) and the volume was made up to 0.6 cm³ with dichloromethane. The solution was then added to *cis*- $[PtMe_2(PMe_2Ph)_2]$ (0.035 g, 0.07 mmol) and the n.m.r. spectrum of the resulting solution was recorded at intervals to monitor the course of reaction.
