# Isolation and Crystal Structure of $\left[R h\left(\mathrm{PPh}_{3}\right)_{3}\left(\mathrm{MeCN}^{2}\right)\right]\left[\mathrm{BF}_{4}\right]$, Acetonitriletris(triphenylphosphine)rhodium(I) Tetrafluoroborate $\dagger$ 

Gillian Pimblett and C. David Garner*<br>Chemistry Department, The University, Manchester M13 9PL William Clegg *

Department of Inorganic Chemistry, The University, Newcastle upon Tyne NE1 7RU

The salt $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ has been isolated as one product of the reaction between $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}(\mathrm{MeCN})_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$ and $\mathrm{PPh}_{3}(1: 4)$, and its structure determined by single-crystal $X$-ray diffraction. The cation possesses an essentially square-planar co-ordination geometry, with the length of the Rh-P bond trans to the acetonitrile ligand [2.261 (3) $\AA$ ] significantly shorter than those of the mutually trans $\mathrm{PPh}_{3}$ groups [2.311 (3) and 2.367 (3) $\AA$ ]. Proton, ${ }^{13} \mathrm{C}$, ${ }^{19} \mathrm{~F}$, and ${ }^{31} \mathrm{P}$ n.m.r. spectra have been recorded for this compound and, with reference to these properties and the crystallographic data, the relationship of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ to the hydrogenation catalyst precursor $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]$ and to a material previously reported as $\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{BF}_{4}$ is discussed.

Rhodium-phosphorus chemistry has been widely investigated, ${ }^{1}$ especially because $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right],{ }^{2}$ popularly known as 'Wilkinson's catalyst,' provided the first efficient route for the homogeneous hydrogenation of alkenes, alkynes, and other unsaturated organic molecules under ambient conditions. ${ }^{3-5}$ As part of a study of the reactions of complexes containing a $\mathrm{Rh}_{2}{ }^{4+}$ centre with phosphines, we report here that the reaction of $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}(\mathrm{MeCN})_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{6}$ with triphenylphosphine gives, as one product, $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$. This compound is of interest because of its similarity to Wilkinson's catalyst, and also because $\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{BF}_{4}$ was reported previously, ${ }^{7}$ but not fully characterised.

## Experimental

Preparation of Acetonitriletris(triphenylphosphine)rhodium(1) Tetrafiuoroborate, $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$.-All solvents were dried and distilled under a dinitrogen atmosphere. Manipulations were carried out using standard Schlenk techniques.

Triphenylphosphine ( $1.04 \mathrm{~g}, 3.96 \mathrm{mmol}$ ) was added to a stirred solution of $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}(\mathrm{MeCN})_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}{ }^{6}(0.49 \mathrm{~g}$, 0.66 mmol ) in methanol ( $40 \mathrm{~cm}^{3}$ ). After ca. 2 h the orange solution was filtered to remove the precipitated $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2}-\right.\right.$ $\left.\mathrm{CMe})_{2}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{MeCN})_{4}\right]\left[\mathrm{BF}_{4}\right]_{2}$. Diethyl ether ( $30 \mathrm{~cm}^{3}$ ) was added to the filtrate to ensure the complete precipitation of this orange product, which was removed by filtration. The resulting yellow filtrate was reduced in volume until a pale yellow powder precipitated. Diethyl ether was added to achieve further precipitation and the powder was collected by filtration and dried in vacuo. This powder was recrystallised from a warm methanol solution by cooling to $c a .20^{\circ} \mathrm{C}$. Small block-like crystals, suitable for $X$-ray crystallographic study, were obtained on controlled addition of diethyl ether to a concentrated solution of the material in methanol. Yield 0.39 g (ca. 30\%).
Subsequently, a more rational synthesis of this compound was developed. The compound $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]^{2}(0.4 \mathrm{~g}, 0.43$ $\mathrm{mmol})$ and $\left[\mathrm{Me}_{3} \mathrm{O}\right]\left[\mathrm{BF}_{4}\right](0.19 \mathrm{~g}, 1.29 \mathrm{mmol})$ were stirred in

[^0]$\mathrm{MeCN}\left(20 \mathrm{~cm}^{3}\right)$. The reaction mixture was stirred under $\mathrm{N}_{2}$ for $c a .24 \mathrm{~h}$ when an orange solution had formed above a pale yellow precipitate. The solution was filtered, concentrated to 10 $\mathrm{cm}^{3}$, and cooled to $c a .5^{\circ} \mathrm{C}$. An orange-yellow precipitate formed on standing. This was collected by filtration and recrystallised from methanol, when pale yellow crystals formed. Yield ca. $0.22 \mathrm{~g}(50 \%)$ (Found: C, 64.6; H, 4.6; N, 1.3; P, 8.9; Rh, 10.3. $\mathrm{C}_{56} \mathrm{H}_{48} \mathrm{BF}_{4} \mathrm{NP}_{3} \mathrm{Rh}$ requires $\mathrm{C}, 66.1 ; \mathrm{H}, 4.8 ; \mathrm{N}, 1.4 ; \mathrm{P}, 9.1$; Rh, 10.1\%).

Crystallography.-Crystal data. $\mathrm{C}_{56} \mathrm{H}_{48} \mathrm{BF}_{4} \mathrm{NP}_{3} \mathrm{Rh}, M=$ 1017.6 , orthorhombic, $a=25.354(3), \quad b=21.439(1), \quad c=$ 18.842(2) $\AA, U=10242 \AA^{3}$ (from $2 \theta$ values of 36 reflections centred at $\pm \omega$ ), $T=291 \mathrm{~K}$, Mo- $K_{\alpha}$ radiation, $\lambda=0.71069 \AA$, space group Pbca, $Z=8, D_{\mathrm{c}}=1.320 \mathrm{~g} \mathrm{~cm}^{-3}$ (all atoms in general positions); yellow block crystal, $0.2 \times 0.4 \times 0.45 \mathrm{~mm}$, $\mu=4.7 \mathrm{~cm}^{-1}$.

Data collection and processing. Stoe-Siemens AED diffractometer, $\omega-\theta$ scan mode with on-line profile fitting, ${ }^{8} 2 \theta_{\text {max. }}=$ $50^{\circ}$, all indices $\geqslant 0$, no absorption or extinction corrections, intensity decay of $c a .10 \%$ corrected from three standard reflections, 8994 non-extinguished reflections, 4552 with $I>3 \sigma(I)$.

Structure analysis and refinement. Patterson and difference syntheses, blocked-cascade refinement on $F, w^{-1}=\sigma^{2}(F)+$ $0.0026 F^{2}$ optimised automatically, rigid idealised hexagons for Ph groups with $\mathrm{C}-\mathrm{C} 1.395 \AA, \mathrm{C}-\mathrm{H} 0.96 \AA$ on $\mathrm{C}-\mathrm{C}-\mathrm{C}$ external bisectors, anisotropic thermal parameters for Rh, P, C, and N, $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$, rigid tetrahedral $\left[\mathrm{BF}_{4}\right]^{-}$with B-F $1.30 \AA$ and common $U_{\text {iso }}$ [refined to $\left.0.309(5) \AA^{2}\right]$, no H atoms for $\mathrm{MeCN}, R=0.078, R^{\prime}=\Sigma w^{\frac{1}{2}}|\Delta| / \Sigma w^{\frac{1}{2}}\left|F_{\mathrm{o}}\right|=0.084$ (observed reflections only), slope of normal probability plot $=1.32$, scattering factors from ref. 9. Programs: SHELXTL, ${ }^{10}$ diffractometer control program by W. C.

Atomic co-ordinates are given in Table 1, selected geometrical parameters in Table 2.

Instrumentation.-N.m.r. spectra were recorded for $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ dissolved in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$; the proton spectrum was obtained on a Varian SC300 spectrometer, and $20.1-\mathrm{MHz}^{13} \mathrm{C}, 75.3-\mathrm{MHz}^{19} \mathrm{~F}$, and $32.4-\mathrm{MHz}^{31} \mathrm{P}$ spectra on a Brüker WP80 spectrometer. The ${ }^{31} \mathrm{P}$ data were recorded for solutions at ca. 200 and 303 K , the ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{19} \mathrm{~F}$ n.m.r. spectra for solutions maintained at $c a .260,230$, and 290 K , respectively.
I.r. spectra were measured on a Perkin-Elmer 577 spectro-

meter for the compound mulled in Nujol and held between NaCl discs. Conductivity measurements were performed for MeCN solutions at $c a .298 \mathrm{~K}$, using a Phillips PW9504/00 conductivity bridge and platinum electrodes.

## Results and Discussion

The compound $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ crystallises as discrete $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]^{+}$cations and $\left[\mathrm{BF}_{4}\right]^{-}$anions. The anion is probably disordered, as is commonly observed for such small, highly symmetrical counter ions: neither individual atomic co-ordinates nor anisotropic thermal parameters could be successfully refined. This disorder and the high thermal motion of some of the cation phenyl-ring carbon atoms are responsible for the high proportion of unobserved reflections.
In the cation (Figure 1) the rhodium(I) atom has an

Figure 1. Structure of the cation of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ projected on the $\mathrm{Rh}_{\mathbf{3}} \mathbf{N}$ mean plane. All phenyl rings follow the same numbering scheme
essentially square-planar $\mathrm{P}_{3} \mathrm{~N}$ co-ordination. In-plane deviations from ideal square-planar co-ordination consist of $\mathbf{P}-\mathbf{R h}-\mathbf{P}$ angles greater than, and $\mathbf{P}-\mathbf{R h}-\mathbf{N}$ angles less than, $90^{\circ}$ as a result of the disparate steric bulk of the $\mathrm{PPh}_{3}$ and MeCN ligands. An out-of-plane distortion towards tetrahedral coordination is very slight: deviations of the atoms from the mean $\mathrm{Rh}_{3} \mathrm{~N}$ plane are: $\mathrm{Rh}-0.002(2) ; \mathrm{P}(1), 0.079(3) ; \mathrm{P}(2)$,

Figure 2. ${ }^{31} \mathrm{P}$ N.m.r. spectrum of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ plus $\mathrm{PPh}_{3}$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 200 K

${ }^{a} \mathrm{X}=\mathrm{MeCN}$ or $\mathrm{Cl} .{ }^{b}$ Root mean square deviation (unweighted) of the $R h P_{3} N$ atoms from their mean plane.
$-0.067(3) ; \mathbf{P ( 3 )}, 0.080(3) ;$ and $N(4),-0.090(10) \AA$. All three $\mathrm{Rh}-\mathrm{P}$ bond lengths are significantly different: the shortest lies trans to the acetonitrile ligand, which forms an essentially linear $\mathrm{Rh}-\mathrm{N}-\mathrm{C}-\mathrm{C}$ arrangement.

Wilkinson's catalyst, $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]$, may be obtained in a red or an orange form, depending on the method of synthesis, ${ }^{2,4}$ and the crystal structures of both have been determined. ${ }^{11}$ The two forms differ in their packing arrangements, in the orientations of the phenyl rings, in the degree of distortion of the square-planar co-ordination towards tetrahedral, and in the closest Rh... H intramolecular contacts. Important features of the co-ordination in both forms and in $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]^{+}$ are compared in Table 3. The $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]^{+}$cation shows much less out-of-plane distortion than either form of [ $\left.\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]$, and a more orderly 'paddle-wheel' arrangement of the $\mathrm{PPh}_{3}$ ligands: thus the three bonds $\mathrm{P}(1)-\mathrm{C}(111)$, $P(2)-C(211)$, and $P(3)-C(321)$ lie approximately in the $\mathrm{RhP}_{3} \mathrm{~N}$ mean plane [subtending angles of 6.5(2), 4.9(2), and $13.0(2)^{\circ}$ respectively with it], and the phenyl rings mesh together around the co-ordination plane (Figure 1). The difference in the $\mathrm{P}(1)-\mathrm{Rh}-\mathrm{N}(4)$ and $\mathrm{P}(3)-\mathrm{Rh}-\mathrm{N}(4)$ angles can also be ascribed to this arrangement of the ligand substituents.

The phenyl-ring arrangement brings several hydrogen atoms
into close proximity with the Rh atom. Each $\mathrm{PPh}_{3}$ ligand has one ortho-H atom within $2.85 \AA$ of $\mathrm{Rh}: \mathrm{H}(136), 2.80 ; \mathrm{H}(236)$, 2.83 ; and $\mathrm{H}(312), 2.81 \AA$ (for the purpose of these calculations, the $\mathrm{C}-\mathrm{H}$ bonds were extended to $1.08 \AA$ ). All other Rh… H distances are $>2.9 \AA$. This contrasts with the two forms of [ $\left.\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]$, for each of which one particularly short ortho$\mathrm{H} \cdots \mathrm{Rh}$ distance was observed. ${ }^{11,12}$ Since an idealised geometry for phenyl rings was assumed in all three structure determinations, the significance of the hydrogen-atom positions is, however, questionable.

However, the overall co-ordination geometry at the rhodium in all three complexes is similar, despite the above, secondary, differences in detail.

The i.r. spectrum of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ mulled in Nujol clearly showed absorptions characteristic of $\left[\mathrm{BF}_{4}\right]^{-}$ ( $1160,1095,1055$, and $1000 \mathrm{~cm}^{-1}$ ) and $\mathrm{PPh}_{3}(1435,765,745$, and $700 \mathrm{~cm}^{-1}$ ) moieties.

Conductivity measurements, as a function of concentration of a solution in dried, degassed MeCN , indicated that $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ behaves as a $1: 1$ electrolyte in MeCN solution.

The u.v.-visible spectrum of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ in MeCN solution consists of features with $\lambda_{\text {max. }}\left(\varepsilon / \mathrm{mol}^{-1} \mathrm{~cm}^{-1}\right)$ of: $400(1433), 350(3604), 300(9000), 260(16000)$, and 226 $\mathrm{nm}(19500)$. This profile is very similar to that observed for a solution of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{Cl}\right]$ in MeCN .

The ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{19} \mathrm{~F}$, and ${ }^{31} \mathrm{P}$ n.m.r. spectra recorded for $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution were consistent with the solid-state structure of the cation and anion being retained in solution. The ${ }^{1} \mathrm{H}$ n.m.r. spectrum consists of resonances due to MeCN ( 2.11 p.p.m.) and the two inequivalent $\mathrm{PPh}_{3}$ groups ( 7.5 and 7.3 p.p.m., relative intensity $2: 1$ with shoulders to higher frequency on each resonance). The ${ }^{13} \mathrm{C}$ n.m.r. spectrum manifests signals at $(128.3,129.9)$, (130.1, 131.7), (132.2, 134.0), and (134.3, 134.5) p.p.m., which are assigned to the four inequivalent carbons on each phenyl ring, the doubling (as indicated) resulting from the two inequivalent $\mathrm{PPh}_{3}$ groups. Resonances at 127.8 and 0.4 p.p.m. are assigned to the CN and $\mathrm{CH}_{3}$, respectively, of MeCN , the former showing a significant shift from that ( 119 p.p.m.) of the free ligand in the sense observed ${ }^{6}$ for $\left[\mathrm{M}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2}(\mathrm{MeCN})_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}(\mathrm{M}=\mathrm{Mo}$ or Rh ). The ${ }^{19} \mathrm{~F}$ n.m.r. spectrum comprises a single resonance, 38 Hz in width, at -74 p.p.m. (referenced to $\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}$ ), consistent with the presence of $\left[\mathrm{BF}_{4}\right]^{-}$.

The ${ }^{31} \mathrm{P}$ n.m.r. spectrum of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ in
$\mathrm{CD}_{2} \mathrm{Cl}_{2}$ at 200 K (Figure 2) consists of a doublet of doublets centred at 32.1 p.p.m. and a doublet of triplets (with the central peak of each triplet split by second-order effects ${ }^{13}$ ) centred at 44.3 p.p.m. This pattern is typical of an $\mathrm{A}_{2} \mathrm{BX}$ system; ${ }^{14,15}$ here, A are the mutually trans P atoms, B is the P atom trans to MeCN , and $\mathrm{X}=\mathrm{Rh}$, with $\delta\left(\mathrm{P}_{\mathrm{A}}\right)=32.1$ p.p.m. and $\delta\left(\mathrm{P}_{\mathrm{B}}\right)=$ 44.3 p.p.m. The coupling constants are: $J\left(\mathrm{Rh}-\mathrm{P}_{\mathrm{A}}\right)=136$, $J\left(\mathrm{Rh}^{-}-\mathrm{P}_{\mathrm{B}}\right)=170$, and $J\left(\mathrm{P}_{\mathrm{A}}-\mathrm{P}_{\mathrm{B}}\right)=39 \mathrm{~Hz}$. Also, as shown in Figure 2, at 200 K in $\mathrm{CD}_{2} \mathrm{Cl}_{2},\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]^{+}$does not undergo exchange with $\mathrm{PPh}_{3}$ on the n.m.r. time-scale. However, at 303 K in $\mathrm{CD}_{3} \mathrm{CN}$ the ${ }^{31} \mathrm{P}$ n.m.r. spectrum shows some indication for this exchange.

The reaction of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ with $\mathrm{P}(\mathrm{OMe})_{3}$ has been investigated by ${ }^{31} \mathrm{P}$ n.m.r. spectroscopy. Upon addition of $\mathrm{P}(\mathrm{OMe})_{3}$ to a solution of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]$ [ $\mathrm{BF}_{4}$ ] in $\mathrm{CD}_{3} \mathrm{CN}$ at 303 K , the intensity of the doublet of triplets centred at 44.3 p.p.m. decreased and with a 1:1 molar ratio of the reagents the peaks were completely removed. Concomitantly, two peaks centred at 135 p.p.m. appeared and, at the $1: 1$ ratio, took on the appearance of a doublet of triplets. Therefore, we conclude that $\mathrm{P}(\mathrm{OMe})_{3}$ selectively replaces the $\mathrm{PPh}_{3}$ group trans to MeCN in $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]^{+}$.

The initial synthesis of $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ involves cleavage of the $\mathrm{Rh}-\mathrm{Rh}$ single bond of $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{2^{-}}\right.$ $\left.(\mathrm{MeCN})_{6}\right]\left[\mathrm{BF}_{4}\right]_{2}$, upon reaction with $\mathrm{PPh}_{3}$. This resembles the synthesis of a material of composition $\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{BF}_{4}$, which was isolated as a product of the protonation of $\left[\mathrm{Rh}_{2}\left(\mathrm{O}_{2} \mathrm{CMe}\right)_{4}\right]$ by $\mathrm{HBF}_{4}$, followed by reaction with $\mathrm{PPh}_{3} .{ }^{7}$ The conductance of solutions of this material in $\mathrm{MeNO}_{2}$ solution was significantly less than expected for a $1: 1$ electrolyte and, therefore, coordination of the tetrafluoroborate anion to the metal was postulated. This contrasts with $\left[\mathrm{Rh}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{MeCN})\right]\left[\mathrm{BF}_{4}\right]$ which behaves as a $1: 1$ electrolyte. An important difference in the two syntheses is that the route reported herein commenced with MeCN co-ordinated to the rhodium and this clearly clings
tenaciously throughout the subsequent reaction and recrystallisation from MeOH.

## Acknowledgements

We thank the S.E.R.C. for the award of a studentship (to G. P.) and the Fonds der Chemischen Industrie for financial support (to W. C.). The crystal structure analysis was carried out at the University of Göttingen.
