The interaction of Mn(NBu^t)₃Cl with Li(NHBu^t) under prescribed conditions leads to the manganese(VI) dimer, $[Mn(NBu')_2(\mu-NBu')]_2$ 1 and lithium salts 2, 3 of the manganese(VII) nitrido anion $[Mn(N)(NBu^1)_3]^{2-}$, but the interaction with Li(NHC_eH₃Me₂-2.6) gives the paramagnetic, tetrahedral, spiro manganese(II) complex Mn[N(Bu')=C(H)C_aH₄(Me)NH], 4. The interaction of Mn(NBu')₄Cl with methyllithium or dimethylzinc gives the dimeric methyl compound $[MnMe(NBu^t)(\mu-NBu^t)]_2$ 5, while interaction with ZnR_2 (R = Et, CH₂Bu^t, CH₂CMe₂Ph, CH₂SiMe₃ or CH₂Ph) gives similar alkyls **6–10** respectively. The interaction of 1 with ZnR_2 produces $Mn_2(NBu^t)_2(\mu-NBu^t)_4ZnR$ (R = Me 11 or CH_2Bu^t 12), and with Al_2Me_6 , $Mn_2(NBu^t)_2(\mu-NBu^t)_4AIMe_2$ 13. The interaction of [Li(dme)]_2[Mn(NBu^t)_4] (dme = 1.2-dimethoxyethane) and Al_2Me_6 gives $Mn[(\mu-NBu^t)_2AIMe_2]_2$ 14. The structures of compounds 1, 2, 3, 4, 7, 10 and 11 have been determined by X-ray crystallography. Compound 1 has been shown to be isostructural with its rhenium analogue, although twinning or disorder problems precluded accurate analysis. The nitrido compounds 2 and 3 have a common tetrahedral co-ordination sphere of manganese bonded to one nitride and three imido groups. The lithium cations are bonded to the imido nitrogen atoms, chloride ions and ether oxygen atoms. Compound 4 has a molecular structure which comprises a four-co-ordinate tetrahedral 'spiro' manganese atom chelated by two $N(Bu^t)=C(H)C_sH_3(Me)NH^-$ ligands. The six-membered chelate ring formed is approximately planar and the spiro rings (one generated from the other by the two-fold axis through Mn) are almost perpendicular, with a dihedral angle of 91.5° at the Mn^{II} centre. The two formally single Mn-N bonds are slightly different at 2.036 and 2.135 Å. The alkyl dimers 7 and 10 have closely analogous symmetrical structures, comprising two tetrahedral manganese atoms bridged by two imido groups and each bonded to one terminal imido and one alkyl ligand. With respect to the central Mn,N, unit the two alkyls and the two imides adopt cis or Z arrangements. The geometry of the planar Mn, N, unit in each structure has acute Mn-N-Mn (average 83.6°) and obtuse N-Mn-N (average 96.3°) angles consistent with the presence of direct Mn-Mn interaction, which formally has double bond character. Compound 11 has a molecular structure which contains a two-fold axis passing through the methyl and the Zn and Mn atoms. There is an unusual trigonal-planar Zn" atom bonded to a methyl group and two bridging imido groups; Mn(1), in oxidation state v, is bonded to four bridging imido ligands, and Mn(2), oxidation state VI, is bonded to two bridging and two terminal imido ligands.

The synthesis of $Mn(NBu^{1})_{3}Cl$ and a number of complexes derived by substitution of Cl with other anionic ligands has been described.¹ The syntheses and spectroscopic data and crystal structures of further new compounds derived from $Mn(NBu^{1})_{3}Cl$ are now described. The main reactions are shown in Scheme 1; analytical and physical data for the new compounds are listed in Table 1.

Results and Discussion

Interaction of $Mn(NBu^t)_3Cl$ with Li(NHBu^t).—The products from these reactions are critically dependent upon the conditions. The amido compound $Mn(NBu^t)_3(NHBu^t)$, which is thermally unstable, was characterised only spectroscopically,¹ but lithium salts of the *tert*-butylimido analogue of the manganate(2–) anion were studied by X-ray crystallography. Table 2 lists the conditions for the synthesis of these and the new compounds. The neutral manganese(vi) dimer [Mn(NBu^t)₂(µ-NBu')]₂ 1 is obtained from the reaction in Et₂O. After warming to room temperature the solutions are blue to blue-green and are extremely air and moisture sensitive; no crystalline compounds could be isolated. After removal of Et₂O the ¹H NMR spectrum of the oily residue showed broad Et₂O resonances plus bridging (δ ca. 1.65–1.75) and terminal (δ ca. 1.30-1.40) tert-butylimido groups, these NBu' groups being in a 1:2 ratio. These bands can be attributed to mixtures of $[Mn(NBu^t)_2(\mu-NBu^t)]_2$ and the reduced species $[Li_x(OEt_2)_y]$ $[Mn(NBu')_2(\mu - NBu')]_2 (x = 1 \text{ or } 2, y = 1-3).$ The admission of dry oxygen to a light petroleum solution of the oil causes an instantaneous colour change from green-brown to brown and on work-up essentially quantitative yields of 1 are obtained. Although compound 1 was obtained in other ways by reduction of Mn(NBu^t)₃Cl, e.g. by Na-Hg in tetrahydrofuran (thf),¹ the present method is the most convenient and gives the highest yield.

The brown dimer 1 is air-stable and diamagnetic like its rhenium analogue,² which was the first homoleptic imido compound to be made. It is extremely soluble in hydrocarbon solvents and crystals can be obtained only in low yields. However, the bulk product is sufficiently pure to be used as a starting material. The ¹H NMR spectrum has sharp singlets in a

Scheme 1 Main reactions of Mn(NBu¹)₃Cl. (*i*) LiMe, dme; ZnR₂, thf, R = Me, Et, CH₂Bu¹, CH₂CMe₂Ph, CH₂SiMe₃, CH₂Ph; (*ii*) Li(NHBu¹), dme, to give [Li(dme)]₂[Mn(NBu¹)₄] (ref. 1), then Al₂Me₆ in light petroleum; (*iii*) excess Li(NHC₆H₃Me₂-2,6), dme; (*iv*) excess Li(NHBu¹), dme-light petroleum or thf; (*v*) Li(NHBu¹), Et₂O, then O₂; (*vi*) Al₂Me₆ toluene; (*vii*) ZnR₂, R = Me, CH₂Bu¹, thf

2:1 ratio for the terminal and bridging NBu¹ groups, respectively, at the same δ value as the rhenium analogue. The ¹³C-{¹H} NMR spectrum gives chemical shift difference $\Delta \delta_{C_{Z}-C_{\beta}}$ values ³ of 41.4 and 33.6 for the terminal and bridging groups that are smaller than those for the Mn^{VII} compound (45–50)¹ indicating a less π -acidic metal centre. The diamagnetism can be attributed to spin pairing of the d¹, Mn^{VI} electrons via the bridges or a metal-metal bond.

X-Ray data were collected on a small, rather poor quality crystal, and confirmed analogy with the previously studied $\text{Re}_2(\text{NBu'})_6$ species.² However, as a result of gross disorder or, as we now suspect, twinning, it was only possible to locate the manganese and nitrogen atoms with any confidence. Similar problems had occurred with the Re complex but they were considerably more severe in the case of the present study.

It is of interest that the technetium and rhenium arylimido compounds $[M(NR')_3]_2 R' = 2,6-Pr_2C_6H_3$, have an ethanelike structure with no bridging groups while the $R' = 2,6-Me_2C_6H_3$ compounds have bridges;^{4a} attempts to make the technetium *tert*-butyl analogue were unsuccessful.^{4b}

The formation of 1 probably involves initial conversion of $Mn(NBu')_3Cl$ to $Mn(NBu')_3(NHBu')$ and homolysis (cf. ref. 1 for thermal decomposition products) to give $Mn(NBu')_3$ which then dimerizes. In the presence of excess Li(NHBu') reduction to dimeric anionic $Mn^{V,V1}$ or $Mn^{V,V}$ species could occur, these species then being re-oxidised by O₂ to give 1. The green v,v dianion has been obtained by reduction of 1 using stoichiometric amounts of Li powder in 1,2-dimethoxyethane (dme) and will be described in a later paper along with other anionic and cationic species.

The nitrido anion of manganese(VII), $[Mn(N)(NBu')_3]^{2-}$, was obtained as noted in Table 2 but only when low manganese concentrations in thf or dme-toluene were used and the temperature allowed to reach room temperature very slowly otherwise reduction as above occurs. There is evidently competition between reduction and nitrido complex formation. When the reaction is carried out in toluene-dme, the light petroleum extracts are purple and contain additionally the compound $[Li(dme)]_2[Mn(NBu')_4]$ that was isolated and identified. Two nitrido salts, 2 and 3, with $[Li(OEt_2)]^+$ and $[Li(thf)]^+$ as counter ions respectively have been obtained; both

For compound 3, a refers to molecule 1 and b refers to molecule 2 in the asymmetric unit (consistent labelling exists between the two molecules, although the numbering is given in terms of molecule 3a).

contain LiCl in the lattice. A crystal structure determination confirms that compound 2 in the solid state has the formula $[Li(OEt_2)]_2[Mn(N)(NBu')_3]$ -LiCl. A diagram of the manganese-containing anion is shown in Fig. 1 and selected bond lengths and angles are given in Table 3.

In the anion, the Mn–NBu' bond lengths are similar and all consistent with the imido formulation (rather than, say, an amido possibility) and this, together with the overall formulation of the compound identifies the metal as an Mn^{VII} centre. The Mn–N(imido) bond lengths are also somewhat longer than those in the neutral Mn(NBu')₃X species¹ and this feature, together with the Mn–N–C angles of 130° is consistent with the behaviour of all three imido ligands as 4e bent Mn=N–R rather than linear Mn=NR donors. An 18e configuration for the Mn atom thus derives from the 6e nitride, plus three 4e imides. The lithium ions are normal, four-co-ordinate, with bonds to

Fig. 2 Structure of $Mn[N(Bu^t)=C(H)C_6H_3(Me)NH]_2$ 4

two Cl^- ions plus two imido nitrogens [Li(1)] or to one Cl^- , one O(ether) and two imido nitrogens [Li(2) and Li(3)]. Each imido function makes links to two lithiums.

The crystallographic asymmetric unit for compound 3 has the formula $\text{Li}_6(\text{thf})_4\text{Cl}_2[\text{Mn}(N)(\text{NBu'})_3]_2$ making it analogous to 2. Selected bond lengths and angles for the manganate ions are listed in Table 3. Geometric parameters in the two $[\text{Mn}(N)(\text{NBu'})_3]^2$ ions are very similar to those in compound 2.

The co-ordination environments of the lithium atoms vary in this structure. Thus Li(1), Li(3) and Li(4) have distorted four-fold co-ordination to one Cl, one ether oxygen and two imido nitrogens, but Li(5) and Li(6) make short contacts only to three atoms, one Cl and two imido nitrogens, and Li(2) has only one short contact to an ether oxygen, but longer contacts (*ca.* 3.0 Å) to methyl carbons or more likely the associated hydrogen atoms.

The only other compounds with Mn \equiv N bonds are the porphyrinato species Mn^V(N)(porph), porph(2-) = *p*-meth-oxyphenyl-,⁵ dimethyloctaethyl-⁶ and tetra-*p*-tolyl-porphyrinate,⁷ and the phthalocyaninato (pc) complex, Mn^V(N)(pc);⁸ synthetic methods and reactions of nitrido compounds have been reviewed.⁹

Compounds 2 and 3 are moisture but not oxygen sensitive and they are diamagnetic. The IR spectra have a band at 1044 cm^{-1} , assignable to Mn=N¹⁰ in addition to NBu' and solvent bands.

A reasonable mechanism for the formation of the anion is shown in Scheme 2. The initial formation of $Mn(NBu')_3$ -(NHBu') is followed by deprotonation of the NHBu' group, then a second deprotonation of a CH₃ group by the strongly basic Li(NHBu') leads to elimination of isobutylene (2methylprop-1-ene). A similar elimination of isobutylene was proposed for the synthesis of the nitrido anion [Ru(N)-{Bu'NC(O)NBu'}]⁻ and was detected by its reaction with bromine.¹¹ A thermal elimination reaction from the *tert*butoxide of [W₂(OBu')₇]⁻ to yield a hydrido-oxo species has been recently reported.¹²

Interaction of $Mn(NBu')_3Cl$ with $Li(NHC_6H_3Me_2-2,6)$.— The interaction of this lithium amide and $Mn(NBu')_3Cl$ under conditions similar to those used in the reaction of Li(NHBu')leads to only one isolable product in *ca.* 18% yield. This is the neutral manganese(II) species $Mn[N(Bu')=C(H)C_6H_3(Me)N-H]_2$ 4.

Scheme 2 Formation of $Mn \equiv N$ species by deprotonation reactions and elimination of $Me_2C=CH_2$. (i) + Li(NHBu') - LiCl; (ii) + Li-(NHBu') - Bu'NH₂; (iii) + Li(NHBu') - Bu'NH₂ - Me₂C=CH₂

The structure of 4 is shown in Fig. 2; important bond lengths and angles are given in Table 4. The molecule lies on a two-fold axis of symmetry in the unit cell with a dihedral angle of 91.5° between the two almost planar chelate rings. All hydrogen atoms were experimentally located.

The ligand I is the amino analogue of the well known salicylaldimino ligands Π^{13} and is comparable to the large family of β -difunctional ligands typified by Schiff bases and acetylacetonates as well as N,N' ligands such as \beta-diketimines III¹⁴ and aminotroponiminates IV.¹⁵ In 4, as well as in Schiffbase complexes the presence of the aromatic ring affects the π electron delocalisation in the chelate ring compared to that in acetylacetonates or complexes of type III. This is consistent with the bond lengths in 4; C(7)-N(2) at 1.287 Å is clearly a double bond. However, the C(1)-N(1) distance of 1.343 Å implies some conjugation with the benzene ring, cf. Va, Vb. Of further interest are the Mn-N distances of 2.036(3) and 2.135(3) Å, which are on average similar to those in a high-spin, square-planar manganese(II) porphyrin^{16a} [2.083(2) Å]; both are larger than the distances in the comparable phthalocyaninato complex ^{16b} where Mn^{II} has an intermediate spin state ascribed to the small size of the ligand cavity which would prefer the small Mn radius associated with spin pairing.

Compound 4 is paramagnetic with a moment ca. 2.7 μ_B in solution by Evans' NMR method. It has no NMR spectrum and is EPR silent in toluene from 77 to 293 K. In thf solution there is a temperature-dependent spectrum characteristic for Mn^{II}, g = 1.958, $\alpha_{Mn} = 70$ G. Weak EPR spectra of other Mn^{II} compounds have been rationalized.¹⁷ The compound is very air-sensitive but surprisingly stable thermally, melting without decomposition at ca. 230 °C. The mode of formation of 4 is uncertain: this requires the loss of two H atoms from one o-Me

Mn(2)C(5)C(51)	124.2(4)	119.2(3)

group on each arene ring, the formation of a Bu'N=C(H)moiety that can only come from the Bu'N groups of $Mn(NBu')_3Cl$, as well as Mn^{VII} -Mn^{II} reduction.

A recent chelate, $Mn[N(C_6H_3Pr_{2}^i-2.6)CH_2CH_2N(H)(C_6-H_3Pr_{2}^i-2.6)]_2$, might have appeared to be similar to other N,N' species but it has two short Mn–N interactions (2.394 Å) so that Mn^{II} is quasi-two-co-ordinate.^{18a} It may be noted finally that salicylaldiminato compounds of Mn^{II} are known but their structures are uncertain, some appearing to be dimers or polymers.^{18b}

Alkylation Reactions of $Mn(NBu')_3Cl$.—The reaction of $Mn(NBu')_3Cl$ with lithium alkyls or Grignard reagents in most cases led to reduction or decomposition, but interaction with $Ag(C_6F_5)$ allowed the isolation of the reasonably stable green

Fig. 3 Structure of [Mn(CH₂CMe₃)(NBu^t)(µ-NBu^t)]₂ 7

Fig. 4 Structure of the benzyl complex 10

oil $Mn(NBu^{i})_{3}(C_{6}F_{5})$ that was characterised only spectroscopically.¹ We have now obtained a series of manganese(v) alkyls of formula $[MnR(NBu^{i})(\mu-NBu^{i})]_{2}$ (R = Me 5, Et 6, CH₂Buⁱ 7, CH₂CMe₂Ph 8, CH₂SiMe₃ 9 or CH₂Ph 10). We have been unable to synthesise similar compounds having aryl, allyl or alkynyl groups.

The structures of compounds 7 and 10 have been determined. Both dimers have closely analogous structures (Figs. 3, 4 and Table 5) comprising two tetrahedral manganese atoms bridged by two imido groups and each bonded to one terminal imide and one alkyl. With respect to the central Mn₂N₂ unit the two alkyls and the two imides adopt cis or Z arrangements. This is different to the situation found in the related Tc^{VI} dimer,¹⁹ $[TcMe_2(NR')(\mu-NR')]_2$ (R' = C₆H₃Me₂-2,6), where the two terminal imides adopt a trans or E structure (erroneously described as Z by the authors), but analogous to the *cis* arrangement of the terminal oxo functions in [TcMe2(O)(µ-O)]₂.^{$\overline{20}$} The geometry of the planar Mn_2N_2 unit in each structure, with acute Mn-N-Mn (average 83.5°) and obtuse N-Mn-N (average 96.3°) angles is consistent with the presence of direct Mn-Mn interaction, which formally has double bond character in this Mn^{v} – Mn^{v} dimer. Other geometry parameters are as expected. The terminal imido groups are approaching linearity (Mn-N-C \approx 160°) with Mn-N bond lengths in the range 1.61-1.63 Å, consistent with normal 6e character, and the bridges are close to being symmetrical. The Mn-C-C angles on the neopentyls are 124.2 and 125.8°, slightly enlarged as a result of the steric bulk of the ligand. A small difference in the corresponding angles in the benzyl compound, 113.7 and 119.2° probably reflects different steric environments. The Mn-C

distances, 2.041 and 2.062 Å are shorter than those in the Mn^{IV} species $MnMe_4(dmpe)$ [dmpe = 1,2-bis(dimethylphosphino)ethane]^{21a} and [MnMe₆]^{2-21b} although the latter distances are likely to be affected by Li⁺-H₃C interactions. It is also relevant to compare present distances with those in Mn^{II} alkyls.^{17,22}

The methyl compound 5 was obtained using $ZnMe_2$ or by interaction with 4 equivalents of LiMe in dme at very low temperatures. The other compounds 6–10 were obtained only using zinc dialkyls and even then only in low to moderate (neopentyl) yields. All these compounds are diamagnetic and surprisingly thermally stable; they sublime at 80–100 °C in vacuum to a solid CO₂ probe. The mass spectra (electron impact, EI) show the molecular ions but for 5 and 7 the highest mass fragments are $(M + 14)^+$. Accurate mass measurements indicate that these fragments are due to $M + CH_2$ ions probably formed during the ionization process. Chemical ionization (isobutane) suppresses this fragmentation pathway.

The ¹H NMR spectra of 5–10 are basically similar. The peak at δ ca. 1.9 can be assigned to μ -NBu' and the one at δ ca. 1.1 to terminal NBu' groups, the remainder of the spectra being due to alkyls. In the ¹³C-{¹H} NMR spectra the chemical shift difference $\Delta \delta_{C_{\alpha}-C_{\beta}}$ is ca. 39–40 for terminal and 34–36 for μ -NBu' groups.

Assuming that the pairs of NBuⁱ groups are related by symmetry in both 'cis' (VIa, as found in the solid state, see above) and 'trans' VIb isomers, the presence of only one peak for the bridging and terminal NBuⁱ groups implies the presence of only one isomer in solution. However, after ca. 2 weeks at room temperature compound 5 showed broadened ¹H NMR spectra while 7 had additional peaks in the two imido regions. The spectra of 5 sharpened on heating in [²H₈]toluene and remained so on cooling. The temperature dependence of the spectrum of 7 is more complicated.

The mechanism of formation of 5–10 which involves loss of NBu' groups is not clear. We have been unable to detect any soluble NBu' zinc species or to stop the reaction at the Mn^{VI} oxidation state.

Alkylations of $[Tc(NR')_3]_2$ (R' = C₆H₃Me₂-2,6) with Mg-MeCl result in replacement of one or two arylimido groups per Tc atom with two or four Me groups respectively,¹⁹ without accompanying reduction of the metal. A similar reaction with 1 gives only intractable solids. Reduction has also been observed in the reaction of SnMe₄ with Tc₂O₇ to give $[TcMe_2(O)(\mu-O)]_2$.²⁰

The formation of such thermally stable Mn^{V} compounds with alkyls having β -H atoms is unusual but similar *tert*-butylimido compounds of both Re^{V} and Re^{VII} have been made.²³ A simple explanation for the thermal stability is that the metal atoms are co-ordinatively saturated and pathways for decomposition involving β -H transfer are not available.²⁴

Interaction of 1 with ZnR_2 ($R = Me, CH_2Bu'$) or Al_2Me_6 .— In an attempt to clarify the formation mechanism of the alkyls from $Mn(NBu')_3Cl$ we studied the interaction of 1 with ZnR_2 (R = Me or CH_2Bu'), the idea being that this might show whether it was an intermediate in the formation of the alkyls. In thf, the interaction of 1 with $ZnMe_2$ even in excess yields only the purple mixed-valence $Mn^{VI}Mn^V$ dimer, $Mn_2(NBu')_2(\mu-NBu')_4ZnMe$ 11, in the form of very air-sensitive but thermally robust crystals. The compound is paramagnetic and has the complicated EPR spectrum shown in Fig. 5. The interaction of $Zn(CH_2Bu')_2$ with 1 gave a purple-blue oil 12 that is similar

Fig. 5 X-Band EPR spectrum of the mixed-valence $Mn^{vi}Mn^{v}$ complex $Mn_2(NBu')_2(\mu-NBu')_4ZnMe$ 11 in toluene at 293 K; scale indicates 100 G

Fig. 6 The structure of the zinc complex 11

to 11. The molecular structure of compound 11 is shown in Fig. 6, selected bond lengths and angles are given in Table 6. The molecule lies on a two-fold axis of symmetry and so the trimetallic unit is linear. With an oxidation state of 2 for Zn the manganese centres are formally 5+ and 6+. Inspection of the Mn–N bond lengths shows that whilst those around the central manganese, Mn(1), are very similar, the bridges between Mn(1) and Mn(2) are quite unsymmetrical, with distances involving Mn(2) some 0.1 Å longer than for Mn(1). The terminal Mn(2)-N(3) imido bond length [1.624(2) Å] and near linear Mn–N–C angle $[164.5(2)^{\circ}]$ are consistent with 6e donor character Mn \equiv NBu⁴. The representation of the structure as a resonance between the two related forms VIIa, VIIb describes the structure as Zn^{2+} –Mn⁶⁺–Mn⁵⁺ and accounts quite simply for the bond length distribution.

The reaction of Al_2Me_6 and 1 in toluene also leads to reduction to a Mn^VMn^{VI} compound 13 similar to 11 but with the ZnMe moiety replaced by $AlMe_2$. This compound is also very air sensitive, incapable of being reduced further even with excess Al_2Me_6 and paramagnetic with an EPR spectrum similar to that of 11.

Finally, since $[\text{Li}(\text{dme})]_2[\text{Mn}(\text{NBu}^{1})_4]^1$ is similar to the species $\text{Li}_2[\text{M}(\text{NBu}^{1})_4]$ (M = W, Mo^{25a} or Cr^{25b}), a reaction similar to that described ^{25a} with Al₂Me₆ is expected and indeed the purple, air-sensitive manganese(v1) compound Mn[(μ -NBu')₂AlMe₂]₂ 14 is obtained. It is similar to the structurally characterised tungsten complex, is thermally stable, melting without decomposition at *ca*. 200 °C and sublimes in vacuum to a cold probe at *ca*. 100 °C. The compound is paramagnetic (d¹) with an EPR spectrum characteristic for Mn^{VI} tetrahedral monomers, g = 2.022, $\alpha_{Mn} = 102.9$ G.

By contrast with $[Li(dme)]_2[Mn(NBu')_4]$, compound 14 is easily reduced in thf by Na-Hg giving extremely air-sensitive, turquoise solutions. After evaporation and extraction into light petroleum, cooling and attempted crystallisation gave only an oil, probably $[Li(thf)]_3[Mn(NBu')_4]$, whose EPR spectra

shows reduction of Mn^{VI} to Mn^{V} . Careful treatment of the light petroleum solution with dry oxygen results in oxidation to the purple Mn^{VI} solutions of 14 as shown by comparison of the EPR spectra.

Experimental

Analyses were by the Imperial College microanalytical laboratory. General techniques have been described.¹ Mass spectra were recorded on a VG7070-E spectrometer; IR spectra were in Nujol mulls; NMR spectra were taken on a JEOL-ES-270 spectrometer in C_6D_6 unless otherwise specified. Commercial chemicals were from Aldrich, Jannsen Chimica and Avocado Research Chemicals. The light petroleum used had b.p. 40– 60 °C.

The compound $Mn(NBu^{i})_{3}Cl$ was prepared as described; ¹ Li(NHBuⁱ) and Li(NHC₆H₃Me₂-2,6) were made by interaction of the amine with LiBuⁿ in light petroleum. For ZnR₂ the procedures used for R = Me, CH₂Buⁱ, CH₂CMe₂Ph, CH₂-SiMe₃ and CH₂Ph were as in refs. 26*a*-*e*, respectively. Solvents were dried and degassed by standard methods; all operations were carried out under purified N₂ or Ar, in vacuum or in a Vacuum Atmospheres box.

Di- μ -tert-butylimido-bis[bis(tert-butylimido)manganese(v1)] 1.—To a solution of Mn(NBu¹)₃Cl (1.0 g, 3.3 mmol) in Et₂O (50 cm³) at -78 °C was added via a cannula, a solution of Li(NHBu¹) (0.6 g, 7.6 mmol) in Et₂O (30 cm³). After completion of addition, the reaction mixture was allowed to warm to room temperature over ca. 0.5 h, when the colour changed from green to brown then to green-blue. After stirring (1 h) the volatiles were removed under vacuum and the residue extracted with light petroleum $(3 \times 30 \text{ cm}^3)$. The combined extracts were exposed to dry oxygen for 5 min when the solution became brown. Filtration and evaporation left 1 as a brown, microcrystalline solid that can be handled in air for periods of up to *ca*. 2 h. Yield: 0.85 g, 96%; this product can be used without further purification. Mass spectrum (EI): m/z 536 (M^+) , 521 $(M^+ - \text{Me})$, 450 $(M^+ - \text{NBu}^1 - \text{Me})$, 394 $(M^+ - 2\text{NBu}^1)$. IR: 1200 (Mn=NBu¹), 1016 cm⁻¹ (Mn- μ -NBu¹). NMR: ¹H δ 1.35 [s, 36 H, (CH₃)₃CN], 1.72 [s, 18 H, μ -(CH₃)₃CN]; in CDCl₃, δ 1.30, 1.45; ¹³C-{¹H} δ 32.13 [(CH₃)₃CN], 34.16 [μ -(CH₃)₃CN], 67.80 [μ -(CH₃)₃CN], 73.53 [(CH₃)₃CN].

Bis[(diethyl ether)lithium] [Tris(tert-butylimido)(nitrido)manganate(VII)]-Lithium Chloride (1/1) 2.—To a solution of Mn(NBu')₃Cl (0.3 g, ca. 1 mmol) in dme-toluene (3:1, 60 cm³) at -78 °C was added Li(NHBu') (0.385 g, 4.9 mmol) in the same solvent (40 cm³). The green solution on warming to 10 °C over 12 h became purple-red, then purple {this colour is due to Li₂[Mn(NBu')₄]}. After evaporation the residue was washed with light petroleum until the washings were colourless. The green residue was dissolved in Et₂O (30 cm³), filtered, reduced to 20 cm³ and cooled (-20 °C) to give green, air-sensitive plates. Yield: 0.17 g, ca. 35%. IR: 1190 (Mn=NBu'), 1044 cm⁻¹ (Mn=N). ¹H NMR: δ 3.3 [q, 8 H, (CH₃CH₂)₂O], 1.47 [s, 27 H, (CH₃)₃CN], 1.2 [t, 12 H, (CH₃CH₂)₂O].

Bis[(tetrahydrofuran)lithium] [Tris(tert-butylimido)(nitrido)manganate(vII)]-Lithium Chloride (1/1) 3.—To a solution of Mn(NBu¹)₃Cl (0.25 g, 0.87 mmol) in thf (60 cm³) at -90 °C was added via cannula over 5 min a pre-cooled (-78 °C) solution of Li(NHBu¹) (0.25 g, 3.16 mmol) in thf (50 cm³). Toward the end of the addition, the initial green colour changed to green-brown, and the solution was allowed to reach room temperature over a period of ca. 12 h. After this stage the solution was usually green-brown but on occasion it was purple (see above). Removal of solvent in vacuum and extraction of the residue with light petroleum (3×80 cm³), filtration, concentration to ca. 40 cm³, and slow cooling to -20 °C gave green, rhomboidal prisms. Yield: 0.15 g, ca. 38%. IR: 1188 (Mn=NBu¹), 1044 cm⁻¹ (Mn=N). ¹H NMR: δ 3.63 (br m, 8 H, thf), 1.58 (br m, 8 H, thf), 1.80 [br s, 27 H, (CH₃)₃CN].

Bis(6-tert-butyliminomethyl-o-tolylamido)manganese(II) 4.— To a solution of Mn(NBu¹)₃Cl (0.3 g, ca. 1 mmol) in dmetoluene (3:1, 50 cm³) at -78 °C was added Li(NHC₆H₃Me₂-2,6) (0.64 g, 5 mmol) in dme (20 cm³). The green-brown solution was allowed to reach room temperature over 8 h with stirring. The orange-brown solution was evaporated, the residue extracted with light petroleum (4 × 30 cm³) and the extracts concentrated to ca. 20 cm³. After standing at room temperature until crystallisation started (2–3 d) and subsequent cooling (-20 °C, 7 d), red-orange prisms of 4 were obtained. Yield: 0.08 g, ca. 18%. Mass spectrum (EI): m/z 433 (M^+), 189 [N(H)C₆H₃MeCHNBu¹]. IR: 3369 (N–H), 1605 cm⁻¹ (C=N).

Di- μ -tert-butylimido-bis[(tert-butylimido)methylmanganese-(v)] 5.—Method 1. To a solution of Mn(NBu¹)₃Cl (1 g, 3.3 mmol) in dme-toluene (4:1, 100 cm³) at -90 °C (ethanol + solid CO₂ + liquid nitrogen) was added a pre-cooled (-78 °C) solution of methyllithium [13.2 mmol: 14.5 cm³ of LiMe in Et₂O (0.9 mol dm⁻³) added to dme-toluene 4:1 (ca. 26 cm³)] dropwise over 10 min. The resulting brown-green solution was allowed to warm to room temperature over 18 h when it was brown and stirred for an additional 10 h when it was red-purple. Removal of the volatiles in vacuum and extraction of the residue with light petroleum (2 × 50 cm³), filtration and evaporation left a residue which was dissolved in hot acetonitrile. Filtration and cooling (-20 °C) gave red-purple needles or plates. Yield: 0.3 g, 46% in two crops.

Method 2. To Mn(NBu¹)₃Cl in thf (0.3 g, 1 mmol in 40

cm³) at -78 °C was added ZnMe₂ (0.48 g, 5 mmol in 20 cm³ light petroleum) dropwise. The solution was allowed to warm with stirring for *ca*. 2 d when it was red-purple. Work-up as above gave 0.07 g, 35% yield. Mass spectra: (EI), *m/z* 438 ($M^+ + 14$), 424 (M^+), 409 ($M^+ - Me$), 394 ($M^+ - 2 Me$), 379 ($M^+ - 3 Me$), 364 ($M^+ - 4 Me$); chemical ionization (CI) (isobutane), *m/z* (438, low intensity), 424 (M^+), 409 ($M^+ - Me$), 394 ($M^+ - 2 Me$), 379 ($M^+ - 3 Me$), 364 ($M^+ - 4 Me$); high resolution, *m/z* 424.217, C₁₈H₄₂Mn₂N₄ requires 424.217. NMR: ¹H δ 1.89 [s, 18 H, µ-(CH₃)₃CN], 1.19 [s, 18 H, (CH₃)₃CN], 0.56 (s, 6 H, CH₃); ¹³C-{¹H} δ 13.78 (CH₃), 32.35 [(*CH*₃)₃CN], 35.82 [µ-(*CH*₃)₃CN], 72.96 [(CH₃)₃*C*N], 72.20 [µ-(CH₃)₃*C*N].

Di-µ-tert-butylimido-bis[(tert-butylimido)ethylmanganese(v)] 6.—To a solution of $Mn(NBu^{t})_{3}Cl(0.3 \text{ g}, 1 \text{ mmol in } 40 \text{ cm}^{3} \text{ thf})$ at -78 °C was added ZnEt₂ (5 cm³ of 1 mol dm⁻³ solution in hexanes) and the mixture allowed to warm to room temperature over 1 h. After stirring for 12 h, the solution was evaporated and the residue extracted with light petroleum $(2 \times 10 \text{ cm}^3)$. After filtration the purple-red solution was concentrated to ca. 2 cm³ and chromatographed on neutral Al₂O₃ (deactivated with thf) eluting with light petroleum. After evaporation of the purple fraction the purple oil was distilled and collected on a solid CO₂ cooled probe. Yield: 0.06 g, ca. 25%. The oil was pure according to ¹H NMR spectra. Mass spectrum (EI): m/z 452 (M^+), 423 (M^+ – Et), 408 (M^+ – Et – Me), 393 (M^+ – Et – 2 Me). NMR: ¹H δ 1.93 [s, 18 H, μ -(CH₃)₃CN], 1.73 (t, 6 H, CH₂CH₃), 1.65 (q, 4 H, CH₂CH₃), 1.16 [s, 18 H, (CH₃)₃CN]; ¹³C⁻{¹H $^{\prime}$ δ 25.66 (CH₃CH₂), 32.52 [(CH₃)₃CN], 35.57 (CH₃CH₂), 36.35 [μ -(CH₃)₃CN], 70.49 (μ -Me₃CN), 72.05 (Me_3CN) .

Di- μ -tert-butylimido-bis[(tert-butylimido)neopentylmanganese(v)] 7.—This procedure serves also for compounds 8–10. To Mn(NBu')₃Cl (0.6 g, 2 mmol in 60 cm³ thf) at -78 °C was added Zn(CH₂Bu')₂ (2.1 g, 10 mmol in light petroleum, 10 cm³). After warming to room temperature over 1 h and stirring (16 h) removal of volatiles, extraction of the residue with light petroleum (3 × 20 cm³) and filtration gave a purple solution which was concentrated to ca. 5 cm³, chromatographed on Al₂O₃ with the work-up as above for 5. Yield: 0.21 g, ca. 38%. X-Ray quality crystals were obtained by slow cooling to -20 °C of dilute acetonitrile solutions.

Mass spectra: (EI), m/z 550 (M^+ + 14), 536 (M^+), 478 (M^+ - isobutylene), 465 (M^+ - Me - isobutylene), 450 (M^+ - 2 Me - isobutylene); high resolution, m/z 536.338, C₂₆H₅₈Mn₂N₄ requires 536.342. NMR: ¹H δ 1.96 [s, 18 H, μ -(CH₃)₃CN], 1.93 [s, br, 4 H, CH₂CMe₃], 1.43 [s, 18 H, (CH₃)₃CH₂], 1.12 [s, 18 H, (CH₃)₃CN]; ¹³C-{¹H} δ 32.73 [(CH₃)₃CN], 34.09 [(CH₃)₃CH₂], 36.26 [μ -(CH₃)₃CN], 57.59 [(CH₃)₃CH₂], 70.50 [μ -(CH₃)₃CN], 72.00 [(CH₃)₃CN].

Di-μ-tert-butylimido-bis[(tert-butylimido)(2-methyl-2-phenylpropyl)manganese(v)] 8.—As for 1 from Mn(NBu¹)₃Cl (0.3 g, 1 mmol) and Zn(CH₂CMe₂Ph)₂ (1.65 g, 5 mmol). Final crystallisation from light petroleum. Yield: 0.05 g, 15%. Mass spectrum (EI): m/z 660 (M^+), 527 ($M^+ - CH_2CMe_2Ph$), 456 ($M^+ - NBu^t - CH_2CMe_2$). NMR: ¹H δ 7.42–7.20 (m, 10 H, CH₂CMe₂C₆H₅), 2.01 (s, 4 H, CH₂CMe₂Ph), 1.83 [s, 18 H, μ-NC(CH₃)₃], 1.44 [s, 12 H, CH₂C(CH₃)₂Ph], 1.02 [s, 18 H, NC(CH₃)₃]; ¹³C-{¹H} δ 153.20 [*ipso* (C₆H₅)C(Me)₂CH₂], 129.06, 126.88, 126.12 [other aromatic (C₆H₅)C(Me)₂CH₂], 71.90 (NCMe₃), 70.91 (μ-NCMe₃), 56.98 [CH₂C(Me)₂CH₂], 41.76 [CH₂C(Me)₂Ph], 36.25 [μ-(CH₃)₃CN], 33.95 [CH₂C-(CH₃)₂Ph], 32.47 [(CH₃)₃CN].

Di- μ -tert-butylimido-bis[(tert-butylimido)(trimethylsilylmethyl)manganese(v)] 9.—As for 7 from Mn(NBu')₃Cl (0.3 g) and Zn(CH₂SiMe₃)₂ (1.2 g). Yield: 0.04 g, 15%. Mass spectrum (EI): m/z 568 (M^+), 495 (M^+ – SiMe₃), 481[M^+ –

Me₃Si(CH₂)], 466 (M^+ – Me₃SiCH₂ – Me), 451 (M^+ – Me₃SiCH₂ – 2 Me). NMR: ¹H δ 1.92 [s, 18 H, μ -(CH₃)₃CN], 1.03 [s, 18 H, (CH₃)₃CN], 0.51 [s, 18 H, CH₂Si(CH₃)₃], 0.47 [s, 4 H, CH₂SiMe₃]; ¹³C-{¹H} δ 2.78 [CH₂Si(CH₃)₃], 23.66 [CH₂SiMe₃], 32.96 [(CH₃)₃CN], 35.83 [μ -(CH₃)₃CN)], 71.31 (μ -Me₃CN), 72.53 (Me₃CN).

Di-µ-tert-butylimido-bis[benzyl(tert-butylimido)mangan-

ese(v)] 10.—As for 7 from Mn(NBu¹)₃Cl (0.3 g) and Zn-(CH₂Ph)₂ (1.23 g). After removing the volatiles in vacuum, excess Zn(CH₂Ph)₂ was sublimed to a solid CO₂ cooled probe at 30–40 °C (10⁻² mmHg) and the residue chromatographed; crystallisation was from MeCN. Yield: 0.04 g, ca. 15%. Mass spectrum (EI): m/z 576 (M^+), 485 ($M^+ -$ CH₂Ph), 394 ($M^+ -$ 2CH₂Ph). NMR: ¹H δ 7.32–6.99 (s, 10 H, CH₂C₆H₅), 2.63 (s, 4 H, CH₂Ph), 1.72 [s, 18 H, μ -NC(CH₃)₃], 1.10 [s, 18 H, NC(CH₃)₃]; ¹³C-{¹H} δ 32.3 [(CH₃)₃CN], 36.01 [μ -(CH₃)₃CN], 41.5 (CH₂Ph), 70.50 [μ -(CH₃)₃CN], 72.8 [(CH₃)₃CN], 122.8, 131.2, 151.5 (aromatic).

Interaction of 1 with ZnMe₂, Compound 11.—To a solution of 1 in thf (0.2 g, 0.37 mmol in 20 cm³) was added ZnMe₂ (1.48 cm³ of 1 mol dm⁻³ solution in hexanes, 1.48 mmol). The reaction mixture was stirred at room temperature for 48 h when it was purple. After evaporation of volatiles under vacuum, extraction of the residue with light petroleum (3 × 20 cm³), filtration, concentration to ca. 10 cm³ and cooling (-20 °C), gave redpurple rhomboidal prisms. Yield: 0.15 g, ca. 65%. Mass spectrum (EI): m/z 616 (M^+), 536 ($M^+ -$ MeZn), 521 ($M^+ -$ MeZn - Me), 465 ($M^+ -$ MeZn - Bu'N - Me).

Interaction of 1 with $Zn(CH_2Bu')_2$, Compound 12.—As above from 1 (0.2 g) and $Zn(CH_2Bu')_2$ (0.31 g, 1.48 mmol). After removing the volatiles under vacuum and condensation of highboiling volatiles to a cold probe, the residue was extracted with light petroleum. Filtration and evaporation gave a blue-purple residue which failed to crystallise from non-polar solvent. Mass spectrum (EI): m/z 672 (M^+), 657 (M^+ – Me), 536 (M^+ – CH₂Bu'Zn).

Interaction of 1 with Al₂Me₆, Compound 13.—To a solution of 1 in toluene (0.2 g, 0.37 mmol in 20 cm³) was added Al₂Me₆ (0.3 cm³ of 1.3 mol dm⁻³ solution in light petroleum, 0.39 mmol) and the mixture stirred at room temperature for 6 h when it was purple. Evaporation of the volatiles followed by extraction of the residue with light petroleum, evaporation of the blue filtrate and sublimation to a solid CO₂-cooled probe (oil-bath temperature 100–120 °C, 10⁻² mmHg) gave a purple, air-sensitive, microcrystalline powder. Yield: 0.12 g, ca. 55%. Mass spectra: (EI), m/z 593 (M^+), 578 ($M^+ - Me$), 563 ($M^+ - 2 Me$), 548 ($M^+ - 3 Me$), 533 ($M^+ - 4 Me$); high resolution, m/z593.345, C₂₆H₆₀AlMn₂N₆ requires 593.345.

Interaction of $[\text{Li}(\text{dme})]_2[\text{Mn}(\text{NBu}')_4]$ and Al_2Me_6 , Compound 14.—To a solution of $[\text{Li}(\text{dme})]_2[\text{Mn}(\text{NBu}')_4]^1$ (0.2 g, 0.37 mmol) in light petroleum (30 cm³) was added Al_2Me_6 (1.10 cm³ of 1.7 mol dm⁻³ solution in light petroleum, 1.87 mmol, 5 equivalents) and the purple mixture stirred for 8 h at room temperature. Removal of volatiles in vacuum, extraction of the residue in tetramethylsilane (10 cm³), filtration, concentration to ca. 1 cm³ and cooling (-20 °C), gave purple, extremely air- and moisture-sensitive rhomboidal plates of 14. Yield: ca. 75%. Mass spectra: (EI), m/z 453 (M^+), 438 ($M^+ -$ Me), 423 ($M^+ - 2$ Me), 408 ($M^+ - 3$ Me), 393 ($M^+ - 4$ Me), 378 ($M^+ - 5$ Me); high resolution, m/z 453.290, C₂₀-H₄₈Al₂MnN₄ requires 453.289.

X-Ray Crystallography.—The X-ray measurements were generally made on crystals handled under nitrogen with standard Schlenk procedures, and mounted on glass fibres using a variety of coating and adhesive media (depending on the solubility properties of the crystal being measured). Compounds 2 and 3 were handled in the dry box due to their extreme air sensitivity, and the crystals were coated with dried and degassed Nujol.

The unit-cell and intensity data for all compounds were collected using a Delft-Instruments FAST TV area detector diffractometer and graphite monochromated Mo-Ka radiation $(\lambda = 0.71069 \text{ Å})$ following previously described procedures.² Room-temperature (291 K) data were collected on a dark red air-stable crystal of compound 1, using Araldite as a fixative. Most of the crystals (recrystallised from acetonitrile) were hollow plates. Although the data quality was poor, the compound was found to be isostructural with its rhenium analogue $\text{Re}_2(\text{NBu}')_6$ ² The data for compound 1 were collected in the orthorhombic (body centred) crystal system with cell dimensions a = 11.045(3), b = 17.485(3) and c =34.298(11) Å; these are almost identical to the transformed dimensions for the rhenium analogue, a = 11.193, b = 17.818, c = 35.507 Å. The data were transformed to the lower symmetry triclinic crystal system (as with the Re analogue) in an attempt to minimise the evident serious disorder which existed in all tert-butyl orientations. The structure was solved in the centrosymmetric space group PI and refined to an R factor of 0.12. Completion of the refinement was still not possible due to severe disorder, but the N2MnN2MnN2 core was well defined; thus the species can be assumed to be $[Mn(NBu')_2(\mu-$ NBu')]2. The data collection and refinement details for the other compounds are given in Table 7, including the temperature used for each data collection. All of the structures were solved by direct methods using SHELXS 86²⁸ and refined using full-matrix least squares on F^2 (SHELX 93; scattering factors included in the gamma test version program).²⁹ The data for all of the compounds, except 2 and 3 were corrected for absorption using the program DIFABS³⁰ adapted for FAST geometry.³¹ Compound 2 contains two disordered diethyl ether solvent molecules with high thermal parameters and large thermal ellipsoids for atoms C(4), C(5), C(6) and C(7). All of the

bond lengths in the diethyl ether molecules were fixed (averaged between the two molecules) giving rise to a more meaningful chemical model. Due to the small size of the crystal, compound 3 gave only a weak data set (approximately 76% of the reflections were unobserved). Therefore the value of wR2 for all of the data is high (0.2703). There is disorder evident in some of the thf molecules, leading to high thermal parameters for some

of the carbon atoms. The bond lengths and angles are all well defined and within acceptable limits.

Compound 4 was solved in the enantiomorphic tetragonal space group $P4_{12}(92)$. The structure presented gave a Flack parameter of zero [0.02(4)]. All of the hydrogen atoms for this structure were experimentally located from the difference map. The structure of compound 11 was refined

using the TWIN instruction with a batch scale factor (BASF) of 0.44.

The non-hydrogen atoms were refined anisotropically and all of the hydrogen atoms in compounds 2, 3, 7, 10 and 11 were placed in calculated positions (C-H 0.96 Å, C-C-H and H-C-H 109.5°).

Fractional atomic coordinates are given in Tables 8-13.

Additional material available from the Cambridge Crystallographic Data Centre comprises H-atom coordinates, thermal parameters and remaining bond lengths and angles.
