The W(4f₂) binding energy of [{WCl_a(PhC₂Ph)}₂] 1 obtained by X-ray photoelectron spectroscopy is similar to that of [{WCl4(NPh)}2] and is consistent with a do tungsten(VI) formulation. The reaction of complex 1 and [NEt₂][WCl₅(PhC₂Ph)] 2 with NaOH-EtOH gave cis-stilbene, indicating considerable electron transfer from the metal to the co-ordinated alkyne. Reduction of complex 1 with 2 equivalents of sodium-mercury amalgam in the presence of phosphines gave the complexes [WCl₃(PhC₂Ph)L₂] (L = PMe₃, PMe₂Ph or PMePh₂) with magnetic moments and W(4f₂) binding energies similar to those of the d¹ tungsten(v) organoimido complex [WCl₃(NPh)(PMe₃)₂]. Decomposition of the alkyne complexes with NaOH-EtOH again gave *cis*-stilbene. The crystal structure of [WCl₃(PhC₂Ph)(PMe₃)₂] 3 has been determined. The W-Cl bond trans to the alkyne ligand is long [2.479(3) Å], and the W-C bond lengths [2.011(13) and 2.038(12) Å] indicate a four-electron-donor alkyne ligand. The geometry is similar to that of [WCl₃(NPh)(PMe₃)₂]. Reduction of $[\{WCl_4(PhC_2Ph)\}_2]$ using 4 equivalents of sodium-mercury amalgam in the presence of phosphines gave the complexes $[WCl_2(PhC_2Ph)L_3]$ (L = PMe₃ or PMe₂Ph) which again produced cis-stilbene on decomposition with NaOH-EtOH. The acetylenic carbon resonance at δ 223.15 in the ¹³C-{¹H} NMR spectrum of [WCl₂(PhC₂Ph)(PMe₃)₃] 6 is also indicative of a four-electron-donor alkyne ligand. Its W(4f₂) binding energy is similar to [WCl₂(NPh)(PMe₃)₃] and is consistent with tungsten(IV). A crystal structure of complex 6 shows a similar ligand geometry to [WCl₂-(NPh)(PMe₃)₃], and the W-C bond lengths [2.019(11) and 2.006(11) Å] indicate a four-electrondonor alkyne ligand. Hartree-Fock and scattered wave Xα calculations have been performed on the model complexes $[WCl_5(HC_2H)]^-$ 8, $[WCl_3(HC_2H)(PH_3)_2]$ 9 and $[WCl_2(HC_2H)(PH_3)_3]$ 10. Molecular orbital and population analyses indicated that the acetylene-tungsten bond in each involves $W(5d_\pi) \longrightarrow HC_2H(\pi^*)$ back donation as well as $HC_2H(\pi) \longrightarrow W(5d_\sigma)$ and $HC_2H(\pi_\perp) \longrightarrow W(5d_\pi)$ forward donation, consistent with a four-electron-donor alkyne formalism. Electron withdrawal from the tungsten to the more electronegative CI ligand in complexes 8 and 9 is minimised by rotation of the alkyne away from the meridional vectors. In complex 10 the → W(5d_x) donation and phosphine contributions compensate and no rotation is observed. The total datomic orbital population of complex 8 is close to that of WCI_s, and populations of complexes 9 and 10 step up linearly from this. The computational results support the experimental evidence that $[\{WCl_4(PhC_2Ph)\}_2]$ 1, $[WCl_3(PhC_2Ph)(PMe_3)_2]$ 3 and $[WCl_2(PhC_2Ph)(PMe_3)_3]$ 6 are complexes of tungsten-(VI), -(V) and -(IV) respectively.

Alkyne complexes of the earlier transition metals are well known and have been investigated in detail. Recent work in this field has shown that metal-to-ligand interactions may be sufficiently strong to change the formal oxidation state of the metal and reduce the alkyne ligand. The extent of reduction is such that alkyne complexes have been used as a source of 1,2-alkene dianions in organic synthesis. The alkyne ligand is generally considered to be π bound to the transition metal in a manner similar to the Dewar-Chatt-Duncanson model for olefins (a₁ and b₁ interactions in the local C_{2v} point group), but with the additional possibility of a π_1 alkyne interaction with the metal [a₂ and b₂ interactions in the local C_{2v} point group, (Fig. 1)].

Formally, an alkyne ligand is a two-electron donor if donation is from the π_{\parallel} (acetylene π -parallel) frontier orbital only. If, in addition, strong donation from the π_{\perp} (acetylene π -perpendicular) frontier orbitals to metal atomic orbitals (AOs) occurs as well, then the alkyne is formally a four-electron

Non-SI units employed: $\mu_B = 9.27 \times 10^{-24} \text{ J T}^{-1}$, eV $\approx 1.60 \times 10^{-19} \text{ J}$.

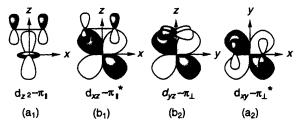

Fig. 1 Frontier MOs for a metal-alkyne complex

donor.¹ This description, however, is exclusive of any back donation from the metal to the alkyne, and therefore may be slightly misleading since this component of the bonding is also important if the formal oxidation state of the central metal is discussed.

In this paper we report experimental and theoretical evidence for the stabilisation of high oxidation states by alkyne ligands. In particular, we show that diphenylacetylene complexes of tungsten exhibit properties and chemistry similar to that found for complexes considered to contain the +6, +5 and +4 oxidation states of this metal. A preliminary account of some of this work has appeared.⁴

Results and Discussion

Synthetic Studies.—The alkyne complex [{WCl4(Ph- $(C_2Ph)_2$ 1 is easily prepared from WCl₆ and diphenylacetylene as a dark red-brown solid which is very sensitive to air and moisture.⁵ It is poorly soluble in non-co-ordinating solvents, but forms 1:1 adducts in tetrahydrofuran (thf), diethyl ether and MeCN which are apparently stable only in solution. Complex 1 reacts with [NEt₄]Cl in CH₂Cl₂ to give a dark red solution, but subsequent removal of the solvent leaves a solid which fails to redissolve. A 2:1 solution of [NEt₄]Cl and [{WCl₄(PhC₂Ph)}₂] in CD₂Cl₂ gives a single set of NMR resonances suggesting the formation of [NEt4][WCl5(Ph- C_2Ph] 2. The ${}^{13}C-\{{}^{1}H\}$ NMR spectrum of complex 2 shows the acetylenic carbons as a single resonance at δ 270.7 which is characteristic of a four-electron-donor alkyne ligand in an electron-deficient alkyne complex.6 In CD₃CN, where the expected complex is [WCl₄(PhC₂Ph)(CD₃CN)], the ¹³C acetylenic resonance occurs at δ 268.4.

In order to make an experimental estimation of the formal oxidation state of tungsten in complex 1 we have determined the W(4f₂) binding energy by X-ray photoelectron spectroscopy (XPS). Its value of 35.1 eV (Table 1) falls within the range for complexes considered to be tungsten(vI), and is close to that measured from the structurally similar do tungsten(vI) organoimido complex [{WCl₄(NPh)}₂] (35.8 eV). High oxidation-state character in complexes 1 and 2 is further emphasised by reaction with aqueous sodium hydroxide in ethanol whereby cis-stilbene is produced, indicating that the coordinated alkyne was in a substantially reduced state.

Reductions of complex 1 in benzene with 1 equivalent of sodium-mercury amalgam in the presence of phosphine ligands afforded the complexes [WCl₃(PhC₂Ph)L₂] (L = PMe₃, PMe₂Ph or PMePh₂) obtained as crystalline orange air-stable solids (Table 2). The complexes exhibit a band in the IR spectrum at about 1660 cm⁻¹ attributable to ν (C \equiv C) of the diphenylacetylene ligand. There are three W-Cl stretching bands in the far IR which are consistent with a *mer* arrangement of metal trichlorides ^{8.9} (Table 2). These complexes exhibit solid-state and solution (Evans' method) magnetic moments consistent with tungsten(ν) species (Table 2). For example,

Table 1 W(4f₂) binding energy for several tungsten complexes

Complex	Binding energy/eV	Formal oxidation state
$[\{WCl_4(PhC_2Ph)\}_2]$ 1	35.1	+6
$[\{WCl_4(NPh)\}_2]$	35.8	+6
$[WCl_3(PhC_2Ph)(PMe_3)_2]$ 3	33.6	+5
$[WCl_3(NPh)(PMe_3)_2]$	34.0	+5
$[WCl_3(PhC_2Ph)(PMe_2Ph)_2]$ 4	33.6	+ 5
$[WCl_2(PhC_2Ph)(PMe_3)_3]$ 6	32.7	+4
$[WCl_2(NPh)(PMe_3)_3]$	32.5	+4

[WCl₃(PhC₂Ph)(PMe₃)₂] 3 shows a solution magnetic moment $\mu_{eff} = 1.51 \, \mu_{B}$ similar to that found for d¹ tungsten oxo complexes ¹⁰ and the d¹ tungsten(v) organoimido complex [WCl₃(NPh)(PMe₃)₂] ($\mu_{eff} = 1.43 \, \mu_{B}$). Further evidence showing that complex 3 is formally tungsten(v) is obtained from the EPR spectrum, where the g value is 1.905 (A_{P} 30 G), which is similar to that found for [WCl₃(NPh)(PMe₃)₂] (g value 1.897 and A_{P} 29 G). 9

X-Ray photoelectron spectroscopy was again employed to obtain the W(4f₂) binding energies of [WCl₃(PhC₂Ph)(PMe₃)₂] 3 and [WCl₃(PhC₂Ph)(PMe₂Ph)₂] 4. (Table 1) The values measured (33.6 eV for both complexes) are similar to that obtained for the tungsten(v) organoimido complex [WCl₃-(NPh)(PMe₃)₂] (34.0 eV) and the recently determined cyano complex [NBu₄]₃[W(CN)₈]¹¹ (33.6 eV). Decomposition of complexes 3 and 4 by aqueous sodium hydroxide in ethanol again led exclusively to *cis*-stilbene.

We have determined the single-crystal structure of [WCl₃(PhC₂Ph)(PMe₃)₂] **3** (Fig. 2). The tungsten atom is in a distorted octahedral array, comprising *trans*-phosphine ligands, the acetylene function, and a meridional arrangement of the three chloro groups. This ligand arrangement is similar to that found for the d¹ organoimido complex [WCl₃(NPh)(PMe₃)₂] and the d¹ oxo complex [WCl₃(O)(PEt₃)₂].¹² Atomic coordinates for complex **3** are listed in Table 3 and selected bond lengths and angles in Table 4, where they are compared to data obtained for [WCl₃(NPh)(PMe₃)₂]. In both complexes the phosphine and chloro ligands lying in the equatorial plane are repelled away from the PhC₂Ph or NPh ligands. The W-Cl bond *trans* to the PhC₂Ph or NPh ligands are considerably

lengthened in comparison with the other W–Cl bonds {for complex 3 W–Cl(1) 2.479(3), W–Cl(2) 2.393(3) Å; for [WCl₃(NPh)(PMe₃)₂]⁹ W–Cl(1) 2.470(2), W–Cl(2) 2.387(2) Å} indicative of a strong *trans* influence. The W–C(1), W–C(2) and C \equiv C bond lengths found for 3 [2.011(13), 2.038(12) and 1.304(15) Å] are not significantly different to those found for [{WCl₄(Me₃SiC₂SiMe₃)}₂]¹³ and [PPh₄][WCl₅(PhC₂H)]-

* Taken from ref. 9(a).

CH₂Cl₂, ¹⁴ which are analogues of complexes 1 and 2. The orientation of the PhC₂Ph ligand in 3 is such that the C-C bond nearly bisects the P(1)-P(2) and Cl(2)-Cl(3) vectors (C-C bond bisection angles 56 and 44°). This feature is also found in [{WCl₄(Me₃SiC₂SiMe₃)}₂] and [PPh₄][WCl₅(PhC₂H)]-CH₂Cl₂, which are formally tungsten(vI), but the C-C bond more equally bisects the two Cl-Cl vectors in these examples. The current features shown by complex 3 are also not significantly different from those exhibited by [WCl₃(PhC₂Ph)(PMe₂Ph)₂] 4.⁴

When a mixture of PMe₃ and [{WCl₄(PhC₂Ph)}₂] 1 is reduced using 4 equivalents of sodium-mercury amalgam the green, air-stable complex [WCl₂(PhC₂Ph)(PMe₃)₃] 6 is obtained. With PMe₂Ph, the reduction gives a medium yield of [WCl₂(PhC₂Ph)(PMe₂Ph)₃] 7 while the reaction apparently fails when PMePh₂ is used. Complexes 6 and 7 are obtained in better yield by reduction of the respective [WCl₃(PhC₂Ph)L₂] complexes with 1 equivalent of sodium-mercury amalgam and the appropriate phosphine.†

Infrared spectra of complexes 6 and 7 each show two W-Cl stretches consistent with cis-oriented chloro ligands. Complex 7 apparently decomposes in solution so NMR data only for 6 were obtained. The ¹H NMR spectrum shows the PMe₃ ligand methyl resonance as a 2:1 triplet and doublet consistent with a mer-phosphine configuration. In the ¹³C-{¹H} NMR spectrum the phosphine carbon resonances show a doublet and triplet and the acetylenic carbons are a ³¹P-coupled doublet of triplets [2J(CP)_{cis} 6.91, 2J(CP)_{trans} 15.91 Hz]. The position of this multiplet (8 223.15) indicates a four-electron-donor alkyne ligand which is the requirement for an overall 18-electron count for the complex. An XPS spectrum of complex 6 (Table 1) shows a W(4f₂) binding energy of 32.7 eV which is similar to that obtained for the d² organoimido complex [WCl₂(NPh)(PMe₃)₃]¹⁶. These values lie within the range considered to be tungsten(IV).‡, Complex 6 appears to be indefinitely air-stable, but an XPS spectrum of a sample aged in air for several months shows a small amount of surface oxidation product containing tungsten(vi). Decomposition of complexes 6 and 7 by aqueous sodium hydroxide in ethanol again yields cis-stilbene exclusively.

A crystal-structure determination of [WCl₂(PhC₂-Ph)(PMe₃)₃] 6 shows a distorted octahedral geometry with a meridional arrangement of phosphine ligands, all of which lie cis to the diphenylacetylene ligand (Fig. 3). Chloro ligands lie trans to the diphenylacetylene ligand and trans to one phosphine ligand. The complex has a similar geometry to the tungsten(IV) organoimido complex [WCl₂(NPh)(PMe₃)₃]¹⁶ and the oxo complexes $[WBr_2(O)L_3]$ $(L = PMe_2Ph)$ or PMePh₂).¹⁷ Atomic coordinates for complex 6 are listed in Table 5, and bond lengths and angles are compared with those found for [WCl₂(NPh)(PMe₃)₃] 16 in Table 6. In both molecules the equatorial chloro and phosphine ligands are repelled away from the diphenylacetylene or phenylimido ligand [for complex 6, P(2)-W-P(1) 153.8(1) and P(3)-W-C1(2) 163.1(1)°]. The bond length for the chloro ligand trans to the alkyne is significantly longer than the equatorial chloro ligand [W-Cl 2.500(3) and 2.465(3) Å respectively] again indicating a significant trans influence. The W-Cl(1) bond is similar in length to that found for the phenylimido complex [W-Cl(1) 2.501(1) Å] but in this complex the W-Cl bond length for the equatorial chloro ligand is only slightly shorter [2.491(1) Å]. The W-C(1), W-C(2) and C(1)-C(2) bond lengths in $\mathbf{6}$

[†] Initial results of studies using [{MoCl₄(PhC₂Ph)}_x] ¹⁵ show that [MoCl₂(PhC₂Ph)(PMe₃)₃] can be prepared by reduction using 2 equivalents of sodium-mercury amalgam per molybdenum in the presence of PMe₃.

[‡] A more extensive XPS study of tungsten complexes in a variety of different oxidation states is presently being undertaken to verify these observations.

[2.019(11), 2.006(11) and 1.330(16) Å respectively] are similar to those found for the tungsten(v) diphenylacetylene complex 3. The major structural change from complex 3 is the orientation of the diphenylacetylene ligand which now straddles the two trans phosphine ligands.

Theoretical Studies.—Hartree–Fock (HF) 18 calculations were carried out on the model complexes $[WCl_5(HC_2H)]^-$ 8 and $[WCl_2(HC_2H)(PH_3)_3]$ 10, Fig. 4. Scattered wave X_{α} (SWX $_{\alpha}$) 19 single-point calculations were performed on the model complexes 8, 10 and the paramagnetic (open-shell) model complex $[WCl_3(HC_2H)(PH_3)_2]$ 9. The optimised HF internal coordinates of 8 (Table 7), 9 (Table 8) and 10 (Table 9) are in good agreement with the crystal structures. However in complex 10 the calculated C \equiv C distance and C-C-H angle are slightly overestimated (Table 9). As the molecular orbitals (MOs) produced in the SWX $_{\alpha}$ calculations had very similar characteristics to those from the HF calculations, a general

discussion of MO diagrams, population analyses and density plots is appropriate.

Plots of the HF-MO wavefunctions and information from the population analysis show extensive participation from all the carbon p atomic orbitals (AOs) in tungsten-alkyne bonding. The first tungsten-acetylene bonding MO in [WCl₅(HC₂H)] ⁸ [Fig. 5(a)] is composed primarily of the HC\(\ext{\omega}(H\pi_1)\) frontier molecular orbital (FMO), W(d_z) AO and the terminal Cl(p_z) AO. Thus M-alkyne π_{\parallel} bonding is (in part) well represented by the a_1 (C_{2v} point group) MO in Fig. 1. There exists a corresponding totally antibonding interaction at higher energy, which weakens the W-alkyne bond [Fig. 5(b)]. A single MO in which the W(d_{yz})-HC\(\ext{\omega}(H\pi_1)\) component is dominant can be identified (Fig. 6) and related to the b_2 MO of Fig. 1. A MO corresponding to the b_1 MO of Fig.1 has been identified in which the filled W(d_{xz}) AO overlaps with the empty HC\(\ext{\omega}(H\pi_{\mathbb{\omega}})\) FMO in a back-donating interaction [Fig. 7(a)].

stability of this HOMO, which is antibonding with respect to the terminal W-Cl bond. The lowest unoccupied molecular orbital (LUMO) of complex 8 consists only of the nonbonding $W(d_{x^2-y^2})$ AO, thus it appears that the HC=CH a_2 FMO of Fig. 1 plays no role in W-alkyne bonding. The $W(d_{x^2-y^2})$ AO is singly occupied in complex 9 and doubly occupied in complex 10. In the HOMO energy region there are MOs composed primarily of the other ligand AOs, which may contain some

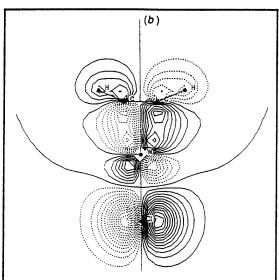

Fig. 7 The W-(HC \equiv CH) π back bonding MOs of [WCl₅(HC₂H)]⁻; MOs in the xz plane [contour difference 0.0125, (a) max + contour 0.1125, min - contour 0.1, (b) max + contour 0.1625, min - contour 0.1375)

contribution from the acetylene FMOs and W(d) AOs, but are not important to the tungsten-alkyne bonding.

As noted earlier the acetylene ligand bisects the meridional vectors in $[\{WCl_4(PhC_2Ph)\}_2]$ and $[WCl_3(PhC_2Ph)(PMe_3)_2]$ but not in [WCl₂(PhC₂Ph)(PMe₃)₃] (Fig. 4). Molecular orbitals with 'cylindrical' symmetry will not affect the acetylene orientation [Fig. 8(a)]. When the acetylene orients along either of the Cl-W-Cl axes in complex 8, additional electron withdrawal from tungsten towards the more electronegative chlorine atoms via a π -type bond occurs, $W(d_{xz})$ – \rightarrow Cl(p) and → Cl(p), which has a destabilising effect on the tungsten-acetylene bond [Figs. 8(b) and 8(c)]. Hence, to minimise net withdrawal, the HC=CH ligand in complex 8 is rotated by 45°. The equatorial Cl ligands now form σ bonds with the $d_{x^2-y^2}$ orbital rather than the d_{xy} orbital [Figs. 9(a) and 9(b)]. Complex 9 has two phosphine ligands (σ donors only) along one axis, 'replacing' two of the chlorine ligands in 8. If the acetylene aligns along either axis, Cl-W-Cl or P-W-P, $W(d_{xz}) \longrightarrow Cl(p)$ or $W(d_{yz}) \longrightarrow Cl(p)$, electron withdrawal occurs [Fig. 8(b) and 8(d)]. To minimise this effect the acetylene is rotated by 56°. This is closer to the P-W-P axis than in complex **8** because of the stabilising $HC \equiv CH(\pi_{\perp}) \longrightarrow W(d_{\nu z})$ donation

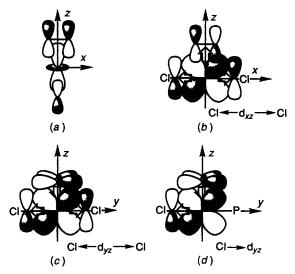

Fig. 8 Qualitative bonding picture for the rotation of the acetylene ligand

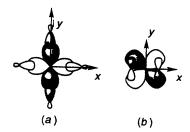

Fig. 9 Representation of the ligand overlap with tungsten; Cl_{σ} overlap with $W_{d_{xx}}$, (b) acetylene with $W_{d_{xx}}$ AOs

[Fig. 8(d)]. In complex 10 the HC \equiv CH $(\pi_{\perp}) \longrightarrow W(d_{yz})$ donor interaction and the phosphine ligand (σ donor) contribution are able to compensate totally for the electron withdrawal of the single Cl atom [Fig. 8(d) only] and therefore, the acetylene aligns along the P-W-P axis (rotation of 90°).

Population analysis shows that electron density donated through the $HC\equiv CH(\pi_{\parallel})$ FMO to the tungsten increases with the increasing number of Cl ligands (Table 10), as expected from simple electronegativity arguments. The electron density donated through the $HC\equiv CH(\pi_{\perp})$ FMO should also increase with the increasing number of Cl ligands. However, the donation is greater than expected for complex 9; this is because the acetylene ligand in complex 9 is rotated 11° more than in complex 8 and as a result the $HC\equiv CH(\pi_{\perp}) \longrightarrow W(d_{yz})$ interaction is enhanced. The total donation of electron density by the acetylene ligands in complexes 8, 9 and 10 well exceeds that donated by the two-electron donor acetylene ligand of the molybdenum complex, $[Mo(C_5H_5)_2(HC_2H)]$, Fig. 10.

The acetylene ligand can compensate the tungsten centre for the effects of other ligands and changes in geometry by altering its acceptance profile (Table 10). In complex 8 there is a shortage of electron density at tungsten and very little back donation occurs. In complexes 9 and 10 the reverse is true. The $HC \equiv CH(\pi_{\perp}^*)$ FMO population accepted for complex 9 is small but significant. In complexes 8 and 9 the $HC \equiv CH(\pi_{\perp}^*)$ FMO overlaps with the (occupied) $W(d_{xy})$ AO which also overlaps with other ligands [Fig. 9(a)]. In contrast the $W(d_{xy})$ of complex 10 does not overlap with other ligands [Fig. 9(b)], only the acetylene $HC \equiv CH(\pi_{\perp}^*)$ FMO is available for accepting the redistribution of any excess electron density, and therefore the population of this FMO is greater.

The d AO populations also provide insight into the bonding. d-Electron density is not localised in a single AO for these

Table 10 Acetylene FMO populations

	Donated		Accepted

complexes (Table 11). The only formally occupied tungsten d AO is the $W(d_{xy})$ in complex 10 although the $W(d_{x^2-y^2})$ AO is partially occupied in complex 9.† The $W(d_{xz})$ AO has a significant population for all of the complexes because it overlaps with the HC≡CH(π_{||}*) FMO which lies above the d manifold and shared electrons are found predominantly in the d AO. Formally, however, this AO is considered to be unoccupied because the $W(d_{xz})$ -HC \equiv CH(π_{\parallel}^*) bonding MO involves back donation from the tungsten atom to the acetylene ligand. The $W(d_{x^2-y^2})$ and $W(d_{z^2})$ AOs are involved with σ bonding and the population of these d AOs will depend on the nature of the ligands. The population of the $W(d_{xy})$ non-bonding AO is expected to be approximately constant for all three complexes, however, for complex 9 it is reduced. This is probably due to the $W(d_{xy})$ AO mixing with the $W(d_{x^2-y^2})$ AO as a result of the greater than 45° rotation of the acetylene ligand in this complex.

In complexes **8**, **9** and **10** the acetylene ligand donates significantly more electron density via the $(HC \equiv CH)\pi_{\perp}$ FMO than, for example, the two-electron donor acetylene ligand in the molybdenum complex $[Mo(C_5H_5)_2(HC_2H)]$ (Table 10). The acetylene ligand in complexes **8**, **9** and **10** can therefore be formally denoted as a four-electron donor. Acceptance by the acetylene in the tungsten and molybdenum complexes studied is significant, since there appears to be a fine tuning mechanism operating which is highly dependent on the individual electronic environment each alkyne ligand experiences.²⁰

It has been found that the spherically averaged electron density around a specific atom changes in a stepwise manner as the formal oxidation number changes.²¹ Orbital population analyses reflect the charge density and therefore the oxidation state of a centre, however, due to the arbitrary nature of partitioning electron density in generating populations the results are relative rather than absolute. For example, the total d AO population of tungsten in WCl₆ is 3.750 e (Fig. 10) which is significantly different from that formally anticipated given the oxidation state of the tungsten is $+vi(d^0)$. Moreover, in the tungsten complexes studied the electron density is highly delocalised, making the assignment of a formal oxidation state to tungsten rather difficult. Comparison of the total d AO population of complexes 8, 9 and 10 with other relevant complexes is made in Fig. 10. The total d AO population of 8 is very close to that of WCl₆,^{4,22} and the populations of complexes 9 and 10 step up from this in a linear relationship. These populations lie well below those for a metal in the $+\pi$ (d⁴) oxidation state. A high-oxidation state formalism is not without precedent for alkyne complexes.^{2,6,22,23} The computational results presented lend support to the proposed

assignment of formal oxidation states +vi, +v and +iv to complexes related to the model compounds 8, 9 and 10 respectively.

Conclusion

The combined results of these studies show that the diphenylacetylene complexes prepared have properties consistent with their formulation as high-valent complexes. The present studies give confirmatory evidence for similar proposals based on previous X-ray structures ^{6,22,23} and the observed similarity between organoimido and alkyne complexes containing alkyl and alkylidene ligands. ^{2c} The alkyne ligand stabilises high oxidation states in a manner similar to organoimido and terminal oxo ligands, and thus the oxidation-state formalism is useful when comparing the properties of such complexes.

Experimental

Experimental procedures and instrumentation have been described.24 Infrared spectra were obtained as Nujol mulls between CsI plates, ¹H and ¹³C-{¹H} NMR spectra were recorded at 400 and 100 MHz respectively in CDCl₃ and EPR spectra were obtained on a Varian E-4 spectrometer operating at 9.5 GHz. Solid-state magnetic moment measurements were made on a Sherwood magnetic susceptibility balance and solution measurements were made at 400 MHz using the Evans' method 25 adapted for a superconducting magnet. 26 X-Ray photoelectron spectra were obtained on an XSAM800 surface analysis instrument. Analytical data were obtained by R. G. Cunninghame and associates, University of Otago, New Zealand. The complex [{WCl₄(PhC₂Ph)}₂] was prepared by refluxing WCl₆ and diphenylacetylene in CH₂Cl₂ containing tetrachloroethylene.⁵ Trimethylphosphine was prepared by reaction of MgMeI on triphenyl phosphite in dibutyl ether ²⁷ and PMe₂Ph and PMePh₂ by reaction of MgMeI on PCl₂Ph or PClPh₂. Benzene, toluene and light petroleum (b.p. 40-60 °C) were distilled under nitrogen, from sodium metal, prior to use.

Preparation of the Complexes.—[WCl₃(PhC₂Ph)(PMe₃)₂] 3. A suspension of [{WCl₄(PhC₂Ph)}₂] (3.6 g, 3.58 mmol) in benzene (150 cm³) was added to sodium—mercury amalgam (Na 0.17g, 7.4 mmol; Hg 45 g) under benzene (50 cm³) containing PMe₃ (1.6 cm³, 14.3 mmol) via a wide-bore cannula. The mixture was stirred rapidly and shaken frequently over a period of 2 h, filtered and the spent amalgam extracted with benzene (2 × 30 cm³). The extracts and filtrate were combined and the volatiles removed giving a yellow-orange crystalline solid. Crude yield 3.7 g. The complex was dissolved in toluene (100 cm³), the solution filtered and crystals obtained by stepwise reduction of the volume. Yield 3.1 g (70%). IR spectrum:

[†] Due to rotation of the acetylene in complex 10 the d_{xy} AO is equivalent to the $d_{x^2-y^2}$ AO in complexes 9 and 10 (the axial system was defined with respect to the acetylene). Thus the d_{xy} AO population is reported as the $d_{x^2-y^2}$ for complex 10 and vice versa.

[WCl₂(PhC₂Ph)(PMe₃)₃] 6. A suspension of [{WCl₄(Ph- C_2Ph)₂] (2.0 g, 1.98 mmol) in benzene (50 cm³) was added to sodium-mercury amalgam (Na 0.2 g, 8.7 mmol; Hg 30 g) under benzene (50 cm³) containing PMe₃ (1.4 cm³, 12.7 mmol) via a wide-bore cannula. The mixture was stirred rapidly and shaken frequently over a period of 3-4 h, the solution filtered and the spent amalgam extracted with benzene $(2 \times 30 \text{ cm}^3)$. The extracts and filtrate were combined and the solvent reduced to a small volume (ca. 10-15 cm³) giving the complex as green microcrystals. Yield 1.8 g (69%). IR spectrum: 1595m, 1560w, 1420m, 1375m, 1340w, 1295m, 1275m, 1070w, 930s, 850w, 780w, 750w, 720m, 705m, 675m, 600w, 515w, 460w, 350w, 278w and 235s cm⁻¹. NMR: 1 H δ 1.52 [d, ${}^{2}J$ (HP) 8.34, 9 H, PMe_3], 1.55 [t, ${}^2J(HP)$ 3.88, 18 H, PMe_3], 6.89 [d, ${}^3J(HH)$ 7.22, 4 H, o-H], 7.11 [t, ${}^{3}J(\text{HH})$ 7.41, 2 H, p-H], 7.27 [t, ${}^{3}J(\text{HH})$ 7.71, 4 H, m-H]; ${}^{13}\text{C}-\{{}^{1}\text{H}\}$ δ 18.58 [t, ${}^{1}J(\text{CP})$ 12.65, PMe₃], 25.98 [d, ¹J(CP) 29.42, PMe₃], 126.07 (p-C), 126.12 (o-C), 127.74 (m-C), 146.58 (ipso-C), 223.15 [dt, ${}^{2}J(CP_{cis})$ 6.91, $^2J(CP_{trans})$ 15.91 Hz, C \equiv C

[WCl₂(PhC₂Ph)(PMe₂Ph)₃] 7. A suspension of [{WCl₄(Ph-C₂Ph)}₂] (0.9 g, 0.89 mmol) in benzene (50 cm³) was reduced with sodium–mercury amalgam (Na 85 mg, 3.7 mmol; Hg 30 g) under benzene (60 cm³) containing PMe₂Ph (0.80 cm³, 5.6 mmol) for 3–4 h as for the preparation of complex 6. Removal of the volatiles from the combined filtrate and spent amalgam extracts (2 × 50 cm³) gave a yellow-green gum which was allowed to stand under light petroleum for 24 h. Extraction of the solid residue with cold toluene (30 cm³) left the complex as green crystals. Yield 0.84 g (55%). IR spectrum: 1590m, 1560w, 1470m, 1420m, 1410w, 1290w, 1275m, 1180w, 1160w, 1100m, 1075w, 1028w, 940s, 905s, 840w, 780w, 740m, 695s, 590w, 570w, 490s, 410m, 345w, 325w, 290m and 260m cm⁻¹.

Hydrolysis Reactions of Complexes 1-4, 6 and 7.—The complex (ca. 0.2 g) was suspended in ethanol (20 cm³) and aqueous sodium hydroxide (ca. 20 cm³, 2 mol dm⁻³) added. The solution was stirred overnight (or refluxed for several hours if dissolution did not occur), filtered and the volatiles removed. The residue was extracted and dried with anhydrous magnesium sulfate. Removal of volatiles gave an oil which had identical ¹H

and ¹³C-{¹H} NMR spectra to an authentic sample of cisstilbene.

Crystallography.—Crystal data for the complexes 3 and 6 are given in Table 12 together with information on instrumentation, data collection and structure determination. Data collection on an Enraf-Nonius CAD-4 diffractometer used graphite-monochromated Mo-K α radiation ($\lambda = 0.710 69 \text{ Å}$) and ω -2 θ scans at variable speed. Lorentz and polarisation corrections were applied using locally written programs and absorption corrections applied from empirical y scans. The structures were solved from Patterson and heavy-atom electron-density syntheses and refined by full-matrix least squares on F using the program SHELX 76.²⁹ The heavier atoms were assigned anisotropic thermal parameters, the light atoms were refined isotropically. Hydrogen atoms were included in calculated positions (C-H 0.95 Å) with common isotropic thermal parameters, and allowed to ride on the atom to which they were attached.

Additional material available from the Cambridge Crystallographic Data Centre comprises H-atom coordinates, thermal parameters and remaining bond lengths and angles.

Theoretical Details.—Hartree-Fock (HF) geometry optimisations were performed using GAUSSIAN 90 18 on the model complexes $[WCl_5(HC_2H)]^-$ 8 and $[WCl_2(HC_2H)(PH_3)_3]$ 10 under the restraint of the $C_{2\nu}$ and C_s point groups respectively, using as initial values data from crystal structures of the complexes, [PPh₄][WCl₅(PhC₂H)]·CH₂Cl₂¹⁴ (Table 7) and [WCl₃(PhC₂Ph)(PMe₂Ph)₂] 4 (Table 8). Non-relativistic pseudopotentials and associated basis sets (decontracted) were used for chlorine ([4s4p]/[3s3p]) and phosphorus [4s4p+(1d)]/[3s3p+(1d)],³⁰ for tungsten a scalar-relativistic pseudopotential and associated basis set ([8s7p6d]/[6s5p3d]) were used. 31 All-electron basis sets were used for C (6-311G) 32a and H (STO-3G). Scattered wave X_{α} (SWX $_{\alpha}$) single point calculations using the program XASW¹⁹ were carried out on the model complexes 8 and 10, and the paramagnetic model complex [WCl₃(HC₂H)(PH₃)₂] 9 (Table 8). Bond distances were taken from the associated crystal structures {complex 9 was modelled on [WCl₂(PhC₂Ph)(PMe₃)₃] 6}. Interatomic angles were chosen to ensure local octahedral symmetry at the tungsten and the C≡C-H angle was set to that from the HF optimisation of 9 (Table 5). Calculations were also carried out on the model complex $[Mo(C_5H_5)_2(HC_2H)]$. Bond distances and angles were taken from the crystal structure 33 of the associated complex [Mo(C₅H₅)₂(PhC₂Ph)] and altered to conform to C_{2v} symmetry. The population analysis of Case and Karplus³⁴ was applied to the SWXα results. Optimised HF calculations were used to generate the MO diagrams.
