# Synthesis, characterization and crystal structures of isothiocyanate and carbodimide complexes derived from organomagnesium reagents: insertion into $\mathbf{M g} \mathbf{~}-\mathbf{X}(X=C$ or $N)$ bonds 

B hamidi Srinivas, ${ }^{\mathrm{a}} \mathrm{C}$ hung- C heng C hang, ${ }^{*, \mathrm{a}} \mathrm{C}$ hau- H an C hen, ${ }^{\mathrm{a}} \mathrm{M}$ ichael $\mathrm{Y} . \mathrm{C}$ hiang, ${ }^{\mathrm{a}} \mathrm{I} .-\mathrm{T}$ ing C hen, ${ }^{\mathrm{a}}$ Yu Wang ${ }^{\text {b }}$ and Gene-H siang Lee ${ }^{\text {b }}$<br>a D epartment of Chemistry, $N$ ational Sun $Y$ at-Sen U niversity, $K$ aohsiung, Taiwan, Republic of China<br>${ }^{\mathrm{b}}$ D epartment of C hemistry, N ational Taiwan U niversity, Taipei, Taiwan, Republic of C hina

A series of magnesium-isothiocyanate and -carbodiimide insertion products, $\mathrm{Mg}(\mathrm{SCPhNBu})_{2}(\text { thf })_{2} \mathbf{1}$,
 been prepared by the stoichiometric reaction between $\mathrm{M} \mathrm{gR} \mathrm{R}_{2}\left(\mathrm{R}=\mathrm{Ph}, \mathrm{Et}\right.$ or $\left.\operatorname{Pr} r^{\prime}\right)$ and various isothiocyanates and carbodiimides in tetrahydrofuran (thf) solution. The 1:1 reaction between bis(diisopropylamido)magnesium and 1,3-diisopropylcarbodiimide gave a dinuclear complex $\mathrm{M} \mathrm{g}_{2}\left(\mu-\mathrm{N} \mathrm{Pr}{ }_{2}\right)_{2}\left[\left(\operatorname{Pr}^{\mathrm{i} N}\right)_{2} \mathrm{CN} \mathrm{Pr}_{2}^{\mathrm{i}}\right]_{2} 7$ and a mononuclear complex
 ( $R=\operatorname{Pr}^{\mathrm{i}} 9$ or Et 10 ) were obtained using phenyl isothiocyanate and bis(diethylamido)- or bis(diisopropylamido)magnesium in $1: 1$ stoichiometric ratio. A plausible mechanism for the formation of $\mathbf{7}$ and $\mathbf{8}$ is suggested. Reaction between MgEtBr and PhN CS in diethyl ether gave the dinuclear complex $\mathrm{M} \mathrm{g}_{2}(\mathrm{SCEtN} \operatorname{Ph})_{4}\left(\mathrm{OEt}_{2}\right)_{2}$ 11. All of the complexes were characterized by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ N M R and IR spectroscopy as well as elemental analysis. The crystal structures of $\mathbf{1 , 3 , 8 , 9}$ and $\mathbf{1 1}$ were determined by single-crystal $X$-ray diffraction. The reaction of complex $\mathbf{1}$ with an excess of PhNCO resulted in the cyclotrimerization of phenyl isocyanate to give ( PhNCO$)_{3} \cdot$ thf.

The reaction between carbon dioxide and organometallic compounds is of interest because it provides a one-carbon homologization of the organic group. ${ }^{1}$ A number of synthetic and mechanistic studies have been carried out on the insertion reactions of $\mathrm{CO}_{2}$ into $\mathrm{M}-\mathrm{C}, \mathrm{M}-\mathrm{O}, \mathrm{M}-\mathrm{H}$ and $\mathrm{M}-\mathrm{N}$ bonds. ${ }^{2} \mathrm{R}$ ecently we reported the $\mathrm{CO}_{2}$-insertion reactions of polynuclear ethynylbridged aluminium-magnesium compounds which occur selectively at the metal-carbon rather than at the metal-nitrogen bond. ${ }^{3}$ We attributed the high reactivity of the magnesium centre in comparison to that in Grignard reagents to its more electropositive nature. This interesting activity prompted us to investigate the reactivity of magnesium in dialkyl-, diaryl- and dialkylamido-magnesium compounds towards the isoelectronic analogues of $\mathrm{CO}_{2}$ such as isothiocyanates and carbodiimides. While a few reactions of isothiocyanates with magnesium have been reported, ${ }^{4}$ there are no structural data on insertions into the $\mathrm{Mg}-\mathrm{C}$ bond. The insertion reactions of carbodiimides have also been studied extensively for transition metals ${ }^{5}$ yet there is no report available on structurally characterized magnesium imidine compounds.

In this paper we report the synthesis and structural characterization of the products obtained from the insertion reaction of isothiocyanate and carbodiimide with diarylmagnesium compounds. The products are also coupled with migration of the aryl group onto the carbon of isothiocyanate or carbodiimide. The complexes obtained from the insertion reactions of the isothiocyanates are the first where the magnesium is bonded through both nitrogen and sulfur atoms. We also report on the complexes obtained from the reaction of dialkylamidomagnesium and various isothiocyanates and carbodiimides. The reaction of $\mathrm{Mg}(\mathrm{SCPhNBu})_{2}(\text { thf })_{2} 1$ (thf $=$ tetrahydrofuran) with phenyl isocyanate is also examined.

## Results and D iscussion

## Synthesis and characterization

A 1:2 molar ratio of $\mathrm{M} \mathrm{gPh}_{2}$ to $\mathrm{Bu}^{\mathrm{t}} \mathrm{NCS}$ in tetrahydrofuran was
allowed to react for 14-16 h at ambient temperature to yield $\mathrm{Mg}\left(\mathrm{SCPhNBu} \mathrm{u}_{2}\right)_{2}(\text { thf })_{2} \mathbf{1}$ in quantitative yield (Scheme 1). SimiIarly, $\mathrm{Mg}(\mathrm{SCPhNPh})_{2}$ (thf) $2_{2} 2$ was obtained using phenyl isothiocyanate The reaction of diisopropylcarbodiimide and $M g R_{2}\left(R=P h, E t\right.$ or $\left.P r^{i}\right)$, yielded the complexes M g(PriN CR N $\left.\mathrm{Pr}^{\mathrm{i}}\right)_{2}(\text { (thf })_{2}\left(\mathrm{R}=\mathrm{Ph} 3, \mathrm{Et} 4\right.$ or $\mathrm{Pr}^{\mathrm{i}}$ ). The reaction of $\mathrm{Mg}\left(\mathrm{NPr}^{\mathrm{i}}\right)_{2}$ with 1,3-diisopropylcarbodiimide in equimolar ratio gave the unsolvated dinuclear complex $\mathrm{M}_{2}\left(\mu-\mathrm{N} \mathrm{Pr}_{2}^{\mathrm{i}}\right)_{2}\left[\left(\operatorname{Pr}^{\mathrm{i}}\right)_{2} \mathrm{CN} \mathrm{Pr}_{2}\right]_{2} 7$, while a similar reaction with $1: 2$ stoichiometry gave the mononuclear complex Mg g $\left.\left(\operatorname{Pr}^{\mathrm{i} N}\right)_{2} \mathrm{CNPri}\right]_{2}($ thf $)$ 8. The reaction between $\mathrm{Mg}\left(\mathrm{NR}_{2}\right)_{2}\left(\mathrm{R}=\mathrm{Pr}^{\mathrm{i}}\right.$ or Et$)$ and phenyl isothiocyanate in 1:2 stoichiometric ratio gave mononuclear complexes Mg[SC( NPh ) $\left.\mathrm{NR}_{2}\right]_{2}(\text { thf })_{2}\left(\mathrm{R}=\mathrm{Pr}^{\mathrm{i}} 9\right.$ or Et 10) (Scheme 1). The reaction between ethylmagnesium bromide, and phenyl isothiocyanate in $1: 1$ stoichiometric ratio in diethyl ether gave a dinuclear complex $\mathrm{M}_{2}(\mathrm{SCEtN} \mathrm{Ph})_{4}\left(\mathrm{OEt}_{2}\right)_{2}$ 11. All of the complexes have been fully characterized by ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ N M R and IR spectroscopy and elemental analysis while some have been further characterized structurally by single-crystal X-ray diffraction.
The IR spectra of the isothiocyanate complexes are consistent with the presence of isothiocyanate groups in the product. There is no band at ca. $2150 \mathrm{~cm}^{-1}$ attributable to an asymmetric $\mathrm{N}=\mathrm{C}=\mathrm{S}$ stretch and the bands observed are similar to those characteristic bands observed for MeC(S)N HMe (1550, 1200 and $720 \mathrm{~cm}^{-1}$ ). ${ }^{6}$ For the carbodiimide complexes the band at ca. $2100 \mathrm{~cm}^{-1}\left[\mathrm{v}_{\text {asym }}(\mathrm{N}=\mathrm{C}=\mathrm{N})\right]$ of the pure carbodiimide was absent and bands are present in the region $1500-1650 \mathrm{~cm}^{-1}$ assignable to $\mathrm{C}-\mathrm{N}$ stretching and in the region $800-650 \mathrm{~cm}^{-1}$ attributable to metal-carbon stretches.

## Spectroscopic studies

In the ${ }^{1} \mathrm{H}$ NMR spectrum of complex 1 a singlet was observed at $\delta 1.17$ assigned to the methyl protons of the $\mathrm{Bu}^{\mathrm{t}}$ group and a set of multiplets in the aromatic proton region assigned to the phenyl groups. Two singlets at $\delta 1.41$ and 3.80 indicates the presence of co-ordinated thf. For complex 3 the signals at $\delta 1.21$ and 3.37 are assigned as the isopropyl protons and the multi-

$$

## Scheme 1

Scheme 2 R $=$ Pri$^{i}$. (i) $R N=C=N R, 1$ : 1; (ii) dimerization; (iii) excess of carbodiimide, thf
plets in the region $\delta 6.88-7.25$ to aromatic protons. For complex 7 the ${ }^{1} \mathrm{H}$ NMR spectrum is rather distinct with three sets of doublets and septets at $\delta 1.19,1.27,1.47$ and at 3.39, 3.56, 3.87 respectively indicating the presence of three kinds of isopropyl groups (Scheme 2). These isopropyl groups have been identified as those attached to the nitrogen of the amido group, that of the group which arises from migration on to the carbon of the carbodiimide and those of the carbodiimide itself. For complex 8 the ${ }^{1} \mathrm{H}$ NMR spectrum indicates two sets of doublets and septets at $\delta 1.23,1.32$ and $3.48,3.69$ respectively besides two singlets assignable to the thf.

Monomeric complexes 9 and 10 (Scheme 1) showed only one set of doublet and septets at $\delta 1.25,3.88$ for 9 and at $\delta 1.11,3.72$ for 10 which were assigned to the isopropyl and ethyl groups attached to the carbon of phenyl isothiocyanate. A ttempts to obtain structural data on 7 failed due to crystal decay during data collection.

In the ${ }^{1} H$ N M R spectrum the dinuclear complex $\mathbf{1 1}$ gives two sets of signals for methylene groups (one due to $\mathrm{CH}_{2}$ of ethyl at $\delta 2.49$ and the second due to $\mathrm{CH}_{2}$ of diethyl ether at $\delta 3.66$ ) while the methyl protons have merged to give only one triplet at $\delta 1.06$. The aromatic protons were observed in the region $\delta$ 6.8-7.5.
In an attempt to understand the mechanism of formation of the mono- and di-meric species, we have carried out independent experiments using $M g R_{2}$ and $\mathrm{Mg}\left(\mathrm{NR}_{2}\right)_{2}$ and isothiocyanates and carbodiimides. Typically, to a solution of organomagnesium reagents MgPh and $\mathrm{Mg}\left(\mathrm{NPr}_{2}\right)_{2}$, diisopropylcarbodiimide was added either in equimolar ratio or in excess ( $1: 1$ and $1: 2$ stoichiometry). Interestingly, in the case of diarylmagnesium only a monomeric complex $\mathbf{3}$ was obtained while in

\end{gathered}
$$

Scheme 4

Fig. 1 An ORTEP ${ }^{7}$ view of complex 1. Thermal ellipsoids are drawn at the $50 \%$ probability level
the case of dialkylamidomagnesium both dimeric compound 7 and monomeric compound 8 have been obtained (Scheme 2). We attribute the formation of dimer 7 to the stability of $\mathrm{NPr}_{2}^{\mathrm{i}}$ acting as a bridging group in comparison to alkyl or aryl.

It is also interesting that the reaction between MgEtBr and phenyl isothiocyanate yielded a magnesium dimer, 11 , with sulfur as bridging group. In this case only the alkyl group showed preference to bromide in migrating to the carbon of isothiocyanate It is well known that a Schlenk equilibrium (Scheme 3) exists for MgEtBr .
A mechanism for the formation of the dimeric species is given in Scheme 4. In this case $\mathrm{M} \mathrm{gR}_{2}$ reacts with phenyl isothiocyanate in 1:2 molar ratio to form the magnesium dimer, 11 with the sulfur atom of the chelated NCS unit bridging. The formation of a dimeric species (instead of a monomer similar to complex 1) is attributed to steric factors. In the case of complex 1 two thf molecules occupy the apical sites on the magnesium atom which prevents formation of a dimer through sulfur bridges, while in the case of 11 only one diethyl ether group (less bulky) is co-ordinated to each of the magnesium atoms.

## Structures of complexes 1, 3, 8, 9 and 11

$\mathbf{M g} \mathbf{g}(\mathbf{S C P h N B u t})_{2}(\text { thf })_{2} \mathbf{1}$. Complex $\mathbf{1}$ was crystallized from thf solution. A perspective drawing of the structure is shown in Fig. 1. There is a puckering disorder of both axial thf molecules $\left[C(12)-C(15)\right.$ and $\left.C\left(12^{*}\right)-C\left(15^{*}\right)\right]$. The But group exhibits higher thermal parameters than usual which may indicateminor rotational disorder [C(9)-C(11)]. The complex possesses an inversion centre and is best described as having a distorted octahedral geometry around the magnesium atom which is bonded through both sulfur and nitrogen atoms of the ligand. There aretwo molecules of thf at the apical positions. The fourmembered ring $\mathrm{Mg}-\mathrm{S}(1)-\mathrm{C}(1)-\mathrm{N}(1)$ is planar with a mean deviation of $0.02 \AA$. The $\mathrm{S}(1)-\mathrm{C}(1)$ and $\mathrm{C}(1)-\mathrm{N}(1)$ bond lengths, $1.744(6)$ and $1.297(7) \AA$ respectively (Table 1), are between single- and double-bond values ${ }^{8,9}$ (C-S 1.81 and 1.61, C-N 1.51 and $1.26 \AA$ ). This is consistent with the IR spectrum which shows no observable frequencies corresponding to $\mathrm{C}=\mathrm{N}$ beyond $1550 \mathrm{~cm}^{-1}$, which indicates delocalization of the NCS unit. The two thiobenzamide ligands are trans to each other, yet forming an almost coplanar framework. Steric factors are probably responsible for their orientation.

Fig. 2 An ORTEP view of complex 3. Details as in Fig. 1

Fig. 3 An ORTEP view of compound 8. Details as in Fig. 1
$\mathbf{M g}$ (PriN C PhN Prí) $\mathbf{2}_{2}(\mathrm{thf})_{2}$ 3. The magnesium amidine complex $\mathbf{3}$ is structurally similar to $\mathbf{1}$, and also possesses octahedral geometry around the magnesium. However, instead of an inversion centre, the molecule contains a two-fold axis passing through the $\mathrm{O}(1)-\mathrm{Mg}-\mathrm{O}(2)$ axis. The $\mathrm{Mg}-\mathrm{N}$ distances of 2.168(6) and 2.161(6) $\AA$ in the chelated amidine groups are typical $\sigma$-bonding distances. The $\mathrm{C}-\mathrm{N}$ bond lengths $[1.325(10)$ and $1.338(10) \AA]$ are intermediate between the typical $C-N$ (1.47 $\AA$ ) and $C=N(1.27 \AA)$ covalent distances, indicating delocalization over the NCN skeleton. Similar values were found for closely related platinum and palladium complexes ( 1.33 and $1.332 \AA$ ). ${ }^{10.11}$ The N CN bite angle of $114.5(7)^{\circ}$ is close to the corresponding value in $\left[\mathrm{M} \mathrm{O}_{2}(\mathrm{PhNCPhNPh})_{4}\right]\left(117^{\circ}\right) .{ }^{12}$ An ORTEP view of the complex is given in Fig. 2.
$\mathbf{M g [ ( P r i N})_{2} \mathrm{CNPr}^{\mathrm{i}}{ }_{2} \mathbf{h}_{2}$ (thf) $\mathbf{8}$. C omplex $\mathbf{8}$ which was also crystallized from thf solution possesses a square-bipyramidal geometry around magnesium. The diisopropylcarbodiimide ligands act as bidentate chelates forming the basal plane and the solvent thf occupies the axial position. The structure contains a crystallographic two-fold axis passing through $\mathrm{O}(1)$ and Mg . An ORTEP view of the complex is given in Fig. 3. One isopropyl group on each of the carbodiimide ligands is disordered [C (11)-C (13) and two-fold related C(11*)-C(13*)]. Thetwo disordered orientations are related by a mirror plane containing $N(3), C(12)$ and $C(13)$. The elongated ellipsoid of C(11) results from a combination of the two unresolved atomic positions of distorted C (11). The shorter distancebetween C (11) and N (3) as well as the planar arrangement around $C(11)$ is also due to the disorder. A puckering disorder of thf [C(14), C (15), C(14*) and $\mathrm{C}\left(15^{*}\right)$ ] is also observed. A nalogous to complex 3, the $\mathrm{M} \mathrm{g-N}$ distances [2.066(7) and 2.183(6) $\AA$ ] are typical of $\sigma$-bonding. These distances as well as Mg-O(1) [2.098(9) $\AA$ ] are in good agreement with the values for porphyrin ${ }^{13,14}$ or quadridentate Schiff-base derivatives. ${ }^{15}$ The $N(1)-C(1)$ and $N(2)-C(1)$ bond lengths of $1.364(10)$ and $1.306(9) \AA$ again indicate delocaliz-

Fig. 4 An ORTEP view of complex 9. Details as in Fig. 1

Fig. 5 An ORTEP view of complex 11. Details as in Fig. 1
ation over the N CN skeleton. However the small but significant difference between these two bonds and the noticeable shortening of the $\mathrm{Mg} \mathrm{g}-\mathrm{N}(1)$ bond when compared to $\mathrm{Mg}-\mathrm{N}(2)$ seem to support a more localized model with more double-bond character of $\mathrm{Mg}-\mathrm{N}(1)$ and almost singlebond character of $\mathrm{Mg}-\mathrm{N}(2)$. The $\mathrm{N}(3)-\mathrm{C}(1)$ distance of 1.431 (9) $\AA$ is also longer than $N(1)-C(1)$ and $N(2)-C(1)$, consistent with a localized (or at least less delocalized) model. However, disorder of the attached isopropyl group has reduced the reliability of this assignment.
$\mathbf{M g} \operatorname{lSC}(\mathbf{N P h}) \mathrm{NPr}_{2} \mathbf{l}_{2}(\text { thf })_{2}$ 9. The structure of complex $\mathbf{9}$ is monomeric. The thf molecules are disordered having two conformations with occupancies of $50 \%$ each [C(14)-C(17), $50 \%$; $\mathrm{C}\left(14^{\prime}\right)-\mathrm{C}\left(17^{\prime}\right), 50 \%$ ]. Only the $\mathrm{C}(14)-\mathrm{C}(17)$ conformation is shown in the ORTEP plot (Fig. 4). The geometry of the magnesium centre is best described as axially compressed rhombic. The observed trans ligation of the two ligand moieties with $\mathrm{Mg}-\mathrm{S}$ and Mg - N distances of 2.5595(13) and 2.1117(23) $\AA$ respectively is responsible for this geometry. The axial coordination sites are occupied by the oxygen atoms of two thf molecules. By virtue of the presence of an inversion centre at magnesium, the molecule possesses two-fold symmetry. The equatorial donor atoms form a rhombic plane in which the magnesium atom also lies. The Mg g 0 bonds are nearly perpendicular to this plane with $\mathrm{N}-\mathrm{Mg}-\mathrm{O}$ and $\mathrm{S}-\mathrm{Mg}-\mathrm{O}$ bond angles of $90.14(9)$ and $91.13(8)^{\circ}$ respectively. The observed $\mathrm{C}(1)-\mathrm{S}$ and $\mathrm{C}(1)-\mathrm{N}(1)$ distances of $1.736(3)$ and $1.324(4)$ are consistent with $\mathrm{C}-\mathrm{S}$ and $\mathrm{C}-\mathrm{N}$ bonds, clearly establishing the identity of the ligand unit.
$\mathbf{M} \mathbf{g}_{2}(\mathbf{S C E t N P h})_{4}\left(0 \mathrm{Et}_{2}\right)_{2} \mathbf{1 1}$. The structure of the complex $\mathbf{1 1}$ consists of discrete dimeric molecules (Fig. 5). The two magnesium centres are symmetrically related to each other due to

Scheme 5
the presence of a centre of inversion between them. The bidentate PhNCS ligand binds the metal in two different modes. In one the sulfur and nitrogen atoms occupy equatorial positions, and in the second they occupy equatorial and axial positions respectively. The axial sulfur atom is also shared by the other symmetrically related magnesium, to which the sulfur atom is an equatorial donor. The remaining axial position is occupied by the oxygen atom of a solvent diethyl ether molecule. The geometry of the six-co-ordinate magnesium is distorted octahedral. The Mg g S bonds are considerably longer than the $\mathrm{Mg}-\mathrm{N}$ and the axial and equatorial $\mathrm{Mg}-\mathrm{S}$ distances are unequal as could be expected (see Table 1). Unlike in complex 9 , the four equatorial and the central magnesium atoms are not planar; the axial $\mathrm{Mg}-\mathrm{O}$ and $\mathrm{Mg}-\mathrm{S}$ bonds also deviate from perpendicular to the least-squares plane. The Mg - $\mathrm{S}(1)$ distance of the bridging sulfur, 2.690 (3) $\AA$, is considerably longer (nearly $0.16 \AA$ ) than the $\mathrm{Mg}-\mathrm{S}(2)$ distance of the chelated NCS unit. The N CS units chelate to the magnesium with $N(1)-M g-S(1)$ and $N(2)-\mathrm{Mg}-\mathrm{S}(2)$ angles of $63.61(17)$ and $65.65(17)^{\circ}$ respectively. The $S(1)-C(1)$ and $C(1)-N(1)$ bond lengths, $1.768(7)$ and $1.288(10) \AA$, are in the range between single- and double-bond values with the $\mathrm{C}-\mathrm{N}$ bond having more double-bond character than the $\mathrm{C}-\mathrm{S}$ bond.
The dimeric structure of this complex seems to be the result of the two modes of co-ordination exhibited by the ligand, which also preclude the formation of any polymeric species. A comparison of the structural features of $\mathbf{9}$ and $\mathbf{1 1}$ suggests that a similar dimeric structure for the former complex will be sterically disfavoured due to the presence of the bulky diisopropylamido substitution at the carbon atom.

## Reaction of complex 1 with an excess of isocyanate

The reaction of complex $\mathbf{1}$ with an excess of phenyl isocyanate was carried out in an attempt to examine the possibility of ligand replacement (Scheme 5). Surprisingly, the isocyanate ligand trimerizes in the presence of 1 and crystallizes out as the cyanurate in the form of a thf adduct in quantitative yield. Even though the formation of this trimer has been well documented, the nature of the catalyst is quite different. Earlier reports suggest that the conversion of isocyanates into cyanurates uses catalytic amounts of $\mathrm{AlCl}_{3}-\mathrm{NaCl}^{16}$ or $\mathrm{SnR}_{3}\left(\mathrm{OR}^{\prime}\right) .{ }^{17}$ Similar cyclotrimerization reactions have been reported using phenyl isocyanate and dihydrosilanes. ${ }^{18}$ The trimerization of aryl isocyanates can be explained by repeated insertion of PhNCO into the Mg g-0 (thf) bond of complex 1. A fter three insertions, elimination of trimer with reformation of the intermediate magnesium amide occurs (Scheme 6).

## C onclusion

We have demonstrated that a variety of insertion products can be prepared using various organomagnesium reagents and iso-

Scheme 6
thiocyanates and carbodiimides. The reaction between MgR and isothiocyanates/carbodiimides is independent of stoichiometry, while analogous reactions of $\mathrm{Mg}\left(\mathrm{N}_{2}\right)_{2}$ with isothiocyanates/carbodiimides are solely dependent on the stoichiometry. This has been attributed to the probable preference of dialkylamide to act as bridging group to give dimers rather than dialkyl- or diaryl-magnesium compounds. Complex $\mathbf{1}$ acts as a good catalyst for the cyclotrimerization of isocyanates.

## Experimental

A ll experiments were carried out in a $\mathrm{N}_{2}$-flushed glove-bag, drybox or in vacuo using standard Schlenk techniques. ${ }^{19} \mathrm{~A}$ Il solvents were distilled and degassed prior to use. Phenyl isocyanate, phenyl isothiocyanate, tert-butyl isothiocyanate, 1,3diisopropylcarbodiimide and di-tert-butylcarbodiimide were obtained from A Idrich and used as received. All ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ N M R spectra wererecorded on a Varian V X R -300 spectrometer, chemical shifts being referred to either SiM $\mathrm{e}_{4}\left({ }^{1} \mathrm{H}\right)$ or $\mathrm{C}_{6} \mathrm{D}_{6}\left({ }^{1} \mathrm{H}, \delta 7.15\right.$; ${ }^{13} \mathrm{C}-\left\{{ }^{1} \mathrm{H}\right\}, \delta 128.00$ ), IR spectra as N ujol mulls between K Br discs on a Bio-R ad FTS-40 FT-IR spectrometer. Elemental analyses ( $\mathrm{C}, \mathrm{H}$ and N ) were performed at the A nalytische L aboratorien of H. M alissa und G. Reuter G mbH , Germany. Deviations in the results from cal culated values are attributed to the extremely airsensitive and hygroscopic nature of these compounds. The starting materials $M \mathrm{gR}_{2}\left(\mathrm{R}=\mathrm{Ph}\right.$, Et or $\left.\operatorname{Pr} r^{\mathrm{i}}\right)$ and $\mathrm{M} \mathrm{g}\left(\mathrm{NR} \mathrm{R}_{2}\right)_{2}(\mathrm{R}=\mathrm{Pr}$ or Et ) were prepared according to literature methods. ${ }^{20}$

## Syntheses

$\mathbf{M g}(\mathbf{S C P h N B u})_{2}(\text { thf })_{2}$ 1. Complexes 1-6 were prepared by using a general procedure involving $\mathrm{M} \mathrm{gR}_{2}\left(\mathrm{R}=\mathrm{Ph}, \mathrm{Et}\right.$ or $\left.\mathrm{Pr} \mathrm{r}^{\prime}\right)$ and various isothiocyanates and carbodiimides. In a typical procedure for 1 , a solution of $\mathrm{M} \mathrm{gPh}_{2}(1.78 \mathrm{~g}, 10 \mathrm{mmol})$ in tetrahydrofuran ( $40 \mathrm{~cm}^{3}$ ) was added to a solution of But N CS ( $1.06 \mathrm{~g}, 10 \mathrm{mmol}$ ) in thf ( $10 \mathrm{~cm}^{3}$ ). The resulting solution was stirred for $14-16 \mathrm{~h}$ at ambient temperature, then reduced in volume to $\mathrm{ca} .25 \mathrm{~cm}^{3}$. K eeping the saturated solution at room temperature for 2 d resulted in a $70 \%$ yield of colourless crystals of 1, m.p. $230^{\circ} \mathrm{C}$ (decomp.). $\mathrm{NMR( } \mathrm{C}_{6} \mathrm{D}_{6}, 297 \mathrm{~K}, 300 \mathrm{MHz}$ ): ${ }^{1} \mathrm{H}, \delta 1.17\left[\mathrm{~s}, 8 \mathrm{H}, \mathrm{C}\left(\mathrm{CH}_{3}\right)_{3}\right], 1.41\left(\mathrm{~s}, 8 \mathrm{H}, \mathrm{C}^{3,4} \mathrm{H}_{2}\right.$ of thf), $3.80(\mathrm{~s}, 8$ $\mathrm{H}, \mathrm{C}^{2,5} \mathrm{H}_{2}$ of thf), $7.04\left(\mathrm{~m}, 2 \mathrm{p}-\mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{5}\right), 7.28\left(\mathrm{~m}, 4 \mathrm{~m}-\mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{5}\right)$ and $7.31\left(\mathrm{~m}, 40-\mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{5}\right) ;{ }^{13} \mathrm{C}, \delta 25.47$ ( $\mathrm{C}^{3,4}$ of thf), 31.83

( PhNCO$)_{3} \cdot$ thf. To a thf solution ( $50 \mathrm{~cm}^{3}$ ) of complex $\mathbf{1}(0.52$ $\mathrm{g}, 1 \mathrm{mmol}$ ) was added phenyl isocyanate ( $0.364 \mathrm{~g}, 3 \mathrm{mmol}$ ) and the mixture was stirred for 12 h . A colourless crystalline solid was deposited upon slow cooling. M.p. $210^{\circ} \mathrm{C}$. NMR ( $\mathrm{C}_{6} \mathrm{D}_{6}$, $297 \mathrm{~K}, 300 \mathrm{M} \mathrm{Hz}$ ): ${ }^{1} \mathrm{H}, \delta 1.43$ (s, $8 \mathrm{H}, \mathrm{C}^{3,4} \mathrm{H}_{2}$ of thf), 3.56 ( $\mathrm{s}, 8 \mathrm{H}$, $\mathrm{C}^{2,5} \mathrm{H}_{2}$ of thf), $7.12\left(\mathrm{~m}, 4 \mathrm{p}-\mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{5}\right), 7.20(\mathrm{~m}, 8 \mathrm{~m}-\mathrm{H})$ and 7.28 ( $\mathrm{m}, 80-\mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{5}$ ) ; ${ }^{13} \mathrm{C}, \delta 25.77$ ( $\mathrm{C}^{3,4}$ of thf), 67.83 ( $\mathrm{C}^{2,5}$ of thf), $121.28\left(\mathrm{p}-\mathrm{C}\right.$ of $\left.\mathrm{C}_{6} \mathrm{H}_{5}\right), 129.62\left(\mathrm{o}-\mathrm{C}\right.$ of $\left.\mathrm{C}_{6} \mathrm{H}_{5}\right), 131.75(\mathrm{~m}-\mathrm{C}$ of $\mathrm{C}_{6} \mathrm{H}_{5}$ ) and 167.66 ( NCO ). IR ( $\mathrm{Nujol}, \mathrm{cm}^{-1}$ ): 2922w, 1710s, 1490s, 1462s, 1378s, 1073s and 753s (Found: C, 69.45; H , 4.2; N, 11.55. Calc. for $\mathrm{C}_{21} \mathrm{H}_{15} \mathrm{~N}_{3} \mathrm{O}_{3}: \mathrm{C}, 70.6 ; \mathrm{H}, 4.2 ; \mathrm{N}, 11.75 \%$ ). A preliminary X -ray structural analysis confirmed the identity of the compound. H owever, its poor quality prevents publication. F urther attempts to improve the data failed. A $n$ ORTEP drawing is available as supplementary material.

## C rystallography

Suitable single crystals of complexes 1, 3, 8, 9 and 11 were sealed in glass capillaries. Preliminary examination and intensity-data collections were carried out with either a R igaku A F C6S diffractometer (for $\mathbf{1}$ and $\mathbf{8}$ ) or an Enraf-N onius CAD 4 automatic diffractometer (for 3, 9 and 11) using graphitemonochromatized Mo-K $\alpha(\lambda=0.71069 \AA)$ radiation. Intensity data were collected using the $\theta-2 \theta$ scan mode and corrected for absorption and decay. All data suffered different degrees of decay (see Table 2). Linear correction factors were applied in all cases. The structures were solved by SIR $92^{21}$ (for $\mathbf{1}$ and $\mathbf{8}$ ) or by M ULTAN ${ }^{22}$ (for 3, 9 and $\mathbf{1 1}$ ) and refined by full-matrix least squares on F . In the final cycles all non-hydrogen atoms were refined anisotropically and all hydrogen atoms were fixed at idealized positions. A Il calculations were carried out with a SG I R 4000 computer using the TEX SA N program ${ }^{23}$ (for $\mathbf{1}$ and 8) or a microvax 3600 computer using the NRCVAX program ${ }^{24}$ (for 3,9 and 11). The hydrogen atoms of co-ordinated thf in complex 1 were not used due to the common disorder of this molecule. A summary of the data collection and structure solution is given in Table 2.

A tomic coordinates, thermal parameters, and bond lengths and angles have been deposited at the Cambridge Crystallographic Data Centre (CCDC). See Instructions for Authors, J. Chem. Soc., D alton Trans., 1997, I ssue 1. A ny request to the CCDC for this material should quote the full literature citation and the reference number 186/376.

## Acknowledgements

Wethank the National Science Council (NSC), Taiwan, Republic of China for financial support. B. S. thanks the NSC for a post-doctoral fellowship.
