Received 22nd July 1999, Accepted 4th October 1999

Treatment of $[Fe(CO)_5]$ with $Ph_2P(SCMe_3)$ at elevated temperature and pressure afforded, as the major product, the sulfur-capped trinuclear iron cluster $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_6]$ 1, in which two Fe–Fe edges are bridged by phosphido groups and the other by a carbonyl group. Also isolated in low yield from this reaction was the tetranuclear iron complex $[\{Fe_2(\mu-PPh_2)(CO)_6\}_2(\mu_4-S_2)]$ 2, which comprises two phosphido-sulfido-bridged diiron fragments linked by an S–S bond. In contrast it has been demonstrated that the reaction of $[Fe(CO)_5]$ with $Ph_2P(SPh)$ gives the discrete dinuclear complex $[Fe_2(\mu-PPh_2)(\mu-SPh)(CO)_6]$ in which a sulfur–carbon bond has been retained. The reaction of 1 with organo-phosphites and -phosphines results in preservation of the triiron core and monosubstitution of a carbonyl group to give $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_5(L)]$ $[L=P(OMe)_3$ 3a, $P(OPh)_3$ 3b, $PPhMe_2$ 3c or PPh_3 3d]. On reaction of 1 with terminal alkynes, $PPh_2(\mu-PPh_2)(\mu-PPh$

Introduction

Interest in multinuclear transition metal complexes incorporating sulfur atoms has been widespread for a variety of reasons including the range of structural types, their connection with biological processes and their relevance to the hydrodesulfurisation process. In addition a number of complexes of the type $M_3(\mu_3-S)$ (M= transition metal) have been used as efficient catalysts in the cyclotrimerisation of terminal alkynes to give benzene derivatives. The trinuclear species remains intact during the cyclotrimerisation process, presumably due at least in part to the stabilising effect of the sulfur cap. In a similar way the phosphido group (μ -PR₂) has often been used as an inert bridging ligand capable of preventing fragmentation of a polynuclear catalyst during a given organic transformation, although there is a growing list of examples in which the μ -PR₂ group itself can participate in the transformation.

We have been interested in harnessing the potential stability introduced by having both a capping sulfur atom and bridging phosphido groups within the same polynuclear framework. In particular, we have found that the thiophosphine ligand, Ph_2P -(SPh), acts as a convenient source of phosphide and sulfide/ thiolate fragments on treatment with a metal carbonyl complex, the precise nature of the sulfur-containing fragment being dependent on the metal carbonyl complex employed. For example, the reaction of cobalt carbonyl with $Ph_2P(SPh)$ gives a range of sulfur-capped tricobalt complexes $[Co_3(\mu_3-S)-(\mu-PPh_2)(CO)_{7-x}(PPh_3)_x]$ (x=0, 1 or 2) in each of which one

edge of the metal triangle is bridged by a PPh₂ group.⁷ In contrast, treatment of iron carbonyl with Ph₂P(SPh) results in a dinuclear complex, $[Fe_2(\mu-PPh_2)(\mu-SPh)(CO)_6]$, in which the S–C bond is retained within the SPh group.¹⁰ The apparent subtle factors that influence whether S–C bond scission occurs within the generated SPh fragment have prompted us to prepare new Ph₂P(SR) (R = alkyl) ligands and examine their reactions with metal carbonyl complexes.¹¹

In this report we describe the synthesis of the sulfur-capped triiron complex $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_6]$ 1 from the reaction of iron carbonyl with $Ph_2P(SCMe_3)$ and examine the reactions of 1 with triorgano-phosphites, -phosphines and terminal alkynes.

Results and discussion

I. Reaction of [Fe(CO)₅] with Ph₂P(SCMe₃) at elevated temperature and pressure

The reaction of [Fe(CO)₅] with Ph₂P(SCMe₃) in toluene at 423 K and 5 atm CO gives [Fe₃(μ₃-S)(μ-PPh₂)₂(μ-CO)(CO)₆] **1** as the major product along with [{Fe₂(μ-PPh₂)(CO)₆}₂(μ₄-S₂)] **2** (see Scheme 1). Both complexes have been characterised by ¹H, ¹³C, ³¹P NMR and IR spectroscopy and by mass spectrometry and microanalysis (see Table 1 and Experimental section). In addition **1** and **2** have been the subjects of single crystal X-ray diffraction studies. A partial determination of the molecular structure of complex **1** was made; this is depicted in Fig. 1. The X-ray analysis is consistent with the proposed structure ¹² but the poor quality of the data precludes discussion of the structural details.

The spectroscopic properties of complex 1 are consistent with the solid-state structure being maintained in solution. The

^a Recorded in n-hexane solution. ^b ¹H chemical shifts (δ) in ppm relative to SiMe₄ (0.0 ppm), coupling constants in Hz in CDCl₃ at 293 K. c 31P chemical shifts (δ) in ppm relative to external P(OMe)₃ (0.0 ppm) (upfield shifts negative), {1H}-gated decoupled, measured in CDCl₃ at 293 K. To reference relative to 85% H₃PO₄ add 140.2 to tabulated values.

Scheme 1 Products from the reactions of [Fe(CO)₅] with either Ph₂P-(SCMe₃) or Ph₂P(SPh). 10

IR spectrum shows, in addition to three terminal $v_{\rm CO}$ bands, an absorption at lower wavenumber [1875 cm⁻¹] indicating the presence of a bridging carbonyl group. The ³¹P-{¹H} NMR spectrum [relative to P(OMe)₃ (δ 0.0)] of this complex displays one singlet resonance corresponding to the equivalent bridging phosphorus groups [δ 149.9] while the ¹³C-{¹H} NMR spectrum shows, in addition to phenyl resonances, two doublet of doublet carbonyl resonances [δ 214.6{ 2 J(PC) 16, 2 J(P'C) 16} and $208.8\{^2J(PC)\ 12,\ ^2J(P'C)\ 12\ Hz\}$] implying localised fluxionality at room temperature on the NMR timescale. It is possible that the five carbonyl ligands residing on the iron atoms of the iron-iron edge, which is not bridged by a phosphido group, may fluxionate to give one resonance with the other signal being due to the equivalent carbonyl ligands on the remaining iron atom.

The molecular structure of complex 2, which has a crystallo-

bridged by a phosphido group (μ -PPh₂) and a sulfur atom (μ -S). Both Fe(1) and Fe(2) are additionally ligated by three terminal carbonyl groups (one axial and two equatorial), completing a distorted octahedral arrangement around each metal centre. Each of the centrosymmetrically related [Fe₂(μ-P)(μ-S)] cores displays a 'butterfly' arrangement with a dihedral angle of 82.1° between the Fe₂P and Fe₂S planes. The Fe(1)-Fe(2) distance [2.614(1) Å] is identical to that in the diiron complex [Fe₂- $(\mu-PPh_2)(\mu-SPh)(CO)_6$ [2.614(3) Å], which also possesses such a Fe₂PS 'butterfly' core. The only significant difference between the co-ordination of the Fe atoms in the latter structure and in 2 concerns the Fe-S bond lengths (0.03 Å longer in $[Fe_2(\mu-PPh_2)(\mu-SPh)(CO)_6]$ than in 2). The two $[Fe_2-PPh_2](\mu-SPh)(CO)_6$ (μ-PPh₂)(μ-S)(CO)₆] units in 2 are coupled by a S–S bond [S–S' 2.130(2) Å]. It is of note that 2 is thus a rare example of a complex containing a μ_4 -S₂ ligand. ¹³ The bridging Fe₂–S–S–Fe₂ structural unit is also found in the tetranuclear anion ¹⁴ $[{Fe_2(\mu-S)(CO)_6}_2(\mu-S_2)]^{2-}$, which has a longer Fe-Fe bond [2.614(1) 2 vs. 2.518(1) Å] but a shorter S-S bond [2.130(2) 2 vs. 2.164(2) Å] than 2.

The IR spectrum of complex **2** is similar to that of [Fe₂-(μ -PPh₂)(μ -SPh)(CO)₆]¹⁰ with four absorptions in the terminal carbonyl region. The ³¹P-{¹H} NMR spectrum displays one sharp resonance in the range typical for bridging phosphido groups [δ 69.1]⁵ while the FAB mass spectrum shows a molecular ion peak along with fragmentation peaks corresponding to the loss of up to six carbonyl groups.

It is noteworthy that the reaction of [Fe(CO)₅] with Ph₂P-(SPh) yields as the sole product the complex [Fe₂(μ-PPh₂)-(μ-SPh)(CO)₆] in which the sulfur-carbon bond has been retained (see Scheme 1). However, the analogous reaction with Ph₂P(SCMe₃) results in S-C bond cleavage in addition to scission of the S–P bond to give either 1 or 2. The β elimination of butene from similar complexes containing butyl moieties to leave less strongly bonding hydride ligands is widely documented.15 The elimination of isobutene would lead to the formation of $[Fe_2(\mu\text{-PPh}_2)(\mu\text{-SH})(CO)_6]$ in which the weak S–H bond could then easily be cleaved to yield 2 via dimerisation or could react with a further iron carbonyl species to give 1 (Scheme 2). Similar reactivity has been observed in related isolable SH-bridged complexes to give products resulting from cluster build-up. 16 The ligand Ph₂P(SPh) is apparently not able to undergo such a transformation and the S-C bond is retained under similar conditions.

Scheme 2 Proposed pathway for the formation of complexes 1 and 2.

II. Reaction of $[Fe_3(\mu_3\text{-}S)(\mu\text{-}PPh_2)_2(\mu\text{-}CO)(CO)_6]$ 1 with L at elevated temperature

The reaction of $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_6]$ 1 with L $[P(OMe)_3, P(OPh)_3, PPhMe_2 \text{ or } PPh_3]$ in toluene at 373 K affords the complexes $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_5(L)]$ $[L=P(OMe)_3$ 3a, $P(OPh)_3$ 3b, $PPhMe_2$ 3c or PPh_3 3d] in high yield (see Scheme 3). All the complexes have been characterised by 1H , ^{13}C , ^{31}P NMR and IR spectroscopy and by mass spectrometry and microanalysis (see Table 1 and Experimental section). In addition 3c has been the subject of a single crystal X-ray diffraction study.

The molecular structure of $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)-(CO)_5(PPhMe_2)]$ 3c is shown in Fig. 3 and selected bond distances and angles are listed in Table 3. The structure is essentially the same as that for complex 1 with a sulfur atom capping the triiron base and the three metal–metal edges bridged by phosphido [Fe(1)-Fe(3), Fe(2)-Fe(3)] and carbonyl groups [Fe(1)-Fe(2)]. The structure differs from that in 1 in that a pseudo-equatorial terminal carbonyl group on one of the iron atoms that is attached to both a bridging phosphido and a bridging carbonyl group is replaced by a PPhMe₂ ligand.

Attack of PPhMe₂ on complex 1 is notably regiospecific in that, as indicated above, the phosphine prefers to adopt a pseudo-equatorial site on an iron atom that is co-ordinated by both the bridging carbonyl and a phosphido group. The symmetry of 1 means that although PPhMe₂ may attack at Fe(1) to yield the enantiomer of 3c depicted in Fig. 3 and discussed above, substitution of the equatorial carbonyl at Fe(2) is equally probable. It must be assumed that reaction of 1 with PPhMe₂ results in a racemic mixture, which is spontaneously resolved on crystallisation in the chiral space group $P2_12_12_1$.

Scheme 3 Products from the reactions of $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)-(CO)_6]$ 1 with alkynes, phosphites and phosphines.

The spectroscopic properties of complex 3c are consistent with the solid state structure being maintained in solution. On the basis of the close similarity in the spectroscopic data of 3c with those of 3a, 3b and 3d, analogous structures are ascribed to the latter three complexes. In the IR spectra of 3 the bridging carbonyl groups are seen clearly at lower wavenumbers [1837– 1855 cm⁻¹] than the terminal carbonyl groups while molecular ion peaks are observed in the FAB mass spectra of each species. In the ³¹P-{¹H} NMR spectra three resonances are observed correponding to three inequivalent phosphorus environments with the terminal phosphine/phosphite and the remote phosphido group signals taking the form of doublets while the phosphido group adjacent to both gives rise to a doublet of doublets. The ¹³C-{¹H} NMR spectra show, in addition to phenyl and phosphine ligand resonances, two double doublet carbonyl signals at ca. δ 216 and ca. 210. This implies that some localised fluxionality of the carbonyl groups within the complexes occurs at room temperature on the NMR timescale. It is possible that the four carbonyl ligands co-ordinated to the iron atoms of the Fe-Fe edge not bridged by a phosphido group may scramble to give one resonance, with the other being due to the terminal carbonyl ligands on the remaining iron atom. It is noteworthy that even in the presence of an excess of phosphine or phosphite only one terminal carbonyl could be substituted.

III. Reaction of [Fe₃(μ₃-S)(μ-PPh₂)₂(μ-CO)(CO)₆] 1 with RC≡CH at elevated temperature and pressure

The reaction of $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(\mu-CO)(CO)_6]$ 1 with RC=CH $[R=Ph \text{ or } CH_2OH]$ in toluene at 423 K gives the complexes $[Fe_2(\mu-PPh_2CHCRS)(\mu-PPh_2CHCR)(CO)_4]$ [R=Ph 4a or CH_2OH 4b] and, in the case of R=Ph, $[Fe_2(\mu-PPh_2)(\mu-PPh_2CHCPhS)(CO)_5]$ 5 in combined good yield (see Scheme 3). All the complexes have been characterised by 1H , ^{13}C , ^{31}P NMR and IR spectroscopy and by mass spectrometry and

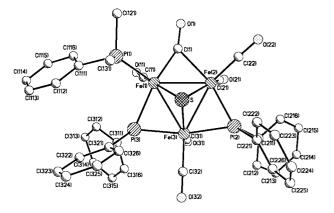

Fig. 3 Molecular structure of $[Fe_3(\mu_3-S)(\mu-PPh_2)_2(CO)_6(PPhMe_2)]$ **3c** including the atom numbering scheme. Hydrogen atoms have been omitted for clarity.

microanalysis (see Table 1 and Experimental section). In addition **4a** has been the subject of a single crystal X-ray diffraction study.

The complex [Fe₂(µ-PPh₂CHCPhS)(µ-PPh₂CHCPh)(CO)₄] **4a** crystallizes with two molecules in the asymmetric unit. The molecules have opposing chirality but are otherwise virtually identical apart from a marked difference in the relative orientation of the phenyl rings C(241)–C(246) and C(211)–C(216) (see Fig. 4). Selected bond distances and angles are given in Table 4 with mean values used in the following discussion.

The structure of complex **4a** consists of an iron–iron vector bridged both by a seven-electron donating ligand [μ -PPh₂-CHCPhS] and by a three-electron donating ligand [μ -PPh₂-CH=CPh] and ligated terminally by carbonyl groups. The μ -PPh₂CHCPhS ligand is incorporated into a five-membered metallacycle [Fe(2)–P(2)–C(3)=C(4)–S(1)] with the olefinic group π co-ordinated [Fe(1)–C(3) 2.150(9); Fe(1)–C(4) 2.08(2) Å] and the sulfur atom σ co-ordinated to the other iron centre

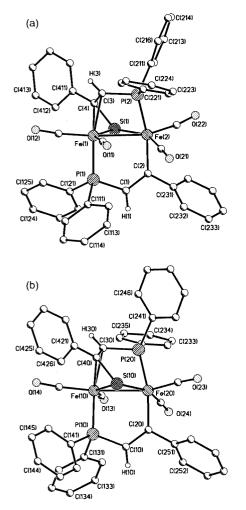

Fig. 4 The molecular structures and atom numbering schemes of the two independent enantiomers (a, molecule 1; b, molecule 2) of [Fe₂-(μ -PPh₂CHCPhS)(μ -PPh₂CHCPh)(CO)₄] **4a**. There is a very marked difference in rotation of the equivalent phenyl rings C(241)–C(246) and C(211)–C(216). Phenyl hydrogen atoms have been omitted for clarity.

[Fe(1)]. In contrast, the μ -PPh₂CH=CPh ligand forms part of a five-membered dimetallacycle [Fe(2)–C(2)=C(1)–P(1)–Fe(1)], in which the olefinic portion is not involved in co-ordination to either metal centre; the short C(1)–C(2) bond length of 1.374(9) Å is consistent with significant C=C character. The distorted octahedral co-ordination geometry at each iron atom is completed by carbonyl groups, two on each metal centre, of which one occupies a pseudo-axial and the other a pseudo-equatorial site (relative to the metal–metal bond). The metal–metal distance [Fe(1)–Fe(2) 2.703(2) Å] is consistent with the presence of a single Fe–Fe bond (as required by the EAN rule) although it is in the upper range for related metallacyclic-bridged diiron complexes. 5,17

While examples of bimetallic complexes bridged by PPh₂-CRCR ligands in which the ligand is incorporated into a metallaphosphabutene ring have been well documented, 9,18 structurally characterised examples in which PPh₂CRCR forms part of a dimetallaphosphapentene ring as in 4a are rare. 7 Furthermore, the cycloferraphosphathiapentene system formed by the $\mu\text{-PPh}_2\text{CHCPhS}$ ligand appears, to the knowledge of the authors, unprecedented.

The spectroscopic properties of complex **4a** are in accordance with the solid state structure being maintained in solution. In the $^{31}P-^{1}H$ NMR spectrum two doublet resonances are seen with chemical shifts [δ -66.2 and -68.2] typical of a diphenylphosphide fragment contained within a metallacycle 7,17c and a coupling constant [$^{3}J(PP)$ 18.3 Hz] characteristic of a phosphorus atom coupling to another phosphorus

through three bonds. The ¹³C-{¹H} NMR spectrum at ambient temperature shows, in addition to signals corresponding to phenyl carbon atoms, four signals at lower field [δ 221.5, 219.9, 214.9, 210.6] due to four inequivalent terminal carbonyl ligands. By comparison with the spectroscopically characterised complex [Fe₂(μ-SPh){μ-PPh₂CHC(CH₂OH)}(CO)₆]⁷ the resonance corresponding to the α -carbon of the non- π -coordinating ligand μ-PPh₂C_BHC_αPh can clearly be identified as a doublet of doublets, ${}^{2}J(PC)$ 35, 35 Hz, at δ 203.6 while the β-carbon atom resonance is masked by that due to the phenyl carbon atoms. On the other hand the α -carbon of the π -coordinated μ -PPh₂C_BHC_aPhS ligand is seen as a doublet, ${}^2J(PC)$ 27 Hz, at δ 157.0 and the β -carbon as a doublet of doublets, $^{1}J(PC)$ 41, $^{3}J(PC)$ 7 Hz, at δ 47.6; these coupling constants are comparable with those found for structurally related µ-PPh₂CHCPhC(O) dicobalt complexes.¹⁹ In the ¹H NMR spectrum of 4a two resonances integrating as one proton each are seen for the two CH protons within the complex. The more downfield doublet of doublet resonance, ²J(PH) 20.4, ⁴J(PH) 5.8 Hz, at δ 6.39 is assigned to the PPh₂CHCPh proton while the singlet at δ 4.08 is assigned to the PPh₂CHCPhS proton. Complex 4b is assigned an analogous structure to that of 4a on the basis of spectroscopic data (see Table 1 and Experimental

The structure of $[Fe_2(\mu-PPh_2)(\mu-PPh_2CHCPhS)(CO)_5]$ 5 has been assigned on the basis of spectroscopic data. The FAB mass spectrum displays a molecular ion peak consistent with the above formulation and fragmentation peaks corresponding to the loss of up to five carbonyl groups. In the ³¹P-{¹H} NMR spectrum two doublet resonances are observed, the downfield resonance $[\delta -1.5, {}^{2}J(PP) 78.0]$ being assigned to a phosphido group bridging two iron atoms 5,10b while the upfield resonance $[\delta -54.2, {}^{2}J(PP) 78.0 \text{ Hz}]$ is comparable with the chemical shift for the phosphorus atom in the PPh2CHCPhS ligand in 4a $[\delta \ ca. -66.0]$. The ¹H NMR spectrum of complex 5 shows resonances corresponding to phenyl protons and a doublet resonance assignable to the olefinic proton at δ 6.88 [2 J(PH) 6.8 Hz, μ-PPh₂CHCPhS], the downfield positioning of this signal suggesting the vinyl group of the μ-PPh₂CHCPhS ligand is not π co-ordinated to an iron atom. The possible formulation of the complex as [Fe₂(μ-SPPh₂)(μ-PPh₂CHCPh)(CO)₅] is rejected due to comparison of the spectroscopic data with those of known complexes containing μ-PPh₂S ligands.^{6,20}

The degradation of the sulfur-capped trinuclear clusters on reaction with alkynes is unusual. ^{4a} Scheme 4 shows a possible pathway that could account for the formation of complexes 4 and 5. Initial insertion of an alkyne group into the metalphosphorus bond in 1 may yield an intermediate complex [Fe₃(μ₃-S)(μ-PPh₂)(μ-PPh₂CH=CR)(μ-CO)(CO)₆] A, with a subsequent internal rearrangement resulting in the formation of the intermediate complex [Fe₃(μ-PPh₂)(μ-PPh₂CH=CRS)(CO)₈] B. The rearrangement of the bridging phosphido group and cleavage of the two iron–iron bonds may then give 5, with further insertion of an alkyne molecule to give 4. On standing, complex 5 readily undergoes a partial decomposition process, in which phenylacetylene is liberated and thus able to recombine with intact molecules of 5 to generate 4a; this suggests that 5 is a precursor to 4a.

It is noteworthy that we have previously observed that treatment of the related complex $[\text{Co}_3(\mu_3\text{-S})(\mu\text{-PPh}_2)(\text{CO})_6(\text{PPh}_3)]$ with $\text{PhC}\equiv\text{CH}$ results in preservation of the tricobalt core and insertion into a metal–phosphorus bond to give $[\text{Co}_3(\mu_3\text{-S})-(\mu\text{-PPh}_2\text{CHCPh})(\text{CO})_6(\text{PPh}_3)]$, a transformation that is consistent with the first step of the proposed reaction pathway. Furthermore, the reaction of $[\text{Fe}_2(\mu\text{-PPh}_2)(\mu\text{-SPh})(\text{CO})_6]$ with $(\text{HOCH}_2)\text{C}\equiv\text{CH}$ has been demonstrated to give the related $(\text{PPh}_2\text{-CHC}(\text{CH}_2\text{OH})-\text{bridged})$ product $[\text{Fe}_2(\mu\text{-SPh})\{\mu\text{-PPh}_2\text{-CHC}(\text{CH}_2\text{OH})\}(\text{CO})_6]$, a step that is related to the iron–phosphorus bond insertion reaction proposed in the conversion of 5 into 4.7

Scheme 4 Possible pathway to account for the formation of complexes 4 and 5 (R = Ph or CH_2OH).

Conclusion

The use of $Ph_2P(SCMe_3)$ in place of $Ph_2P(SPh)$ in the reaction with $[Fe(CO)_5]$ results in sulfur–carbon bond cleavage and yields as the major product the triiron cluster $[Fe_3(\mu_3-S)-(\mu-PPh_2)(\mu-CO)(CO)_6]$ 1. The outcome of reaction of 1 with a range of ligands has been examined and found to depend on the ligand employed. With organo-phosphites and -phosphines

the trinuclear framework is maintained and substitution of a terminal carbonyl group occurs to give 3. In contrast treatment of 1 with alkynes results in breakdown of the Fe₃(μ_3 -S) core to give the bimetallic complexes 4 and 5 in which new sulfurcarbon and phosphorus–carbon bonds have formed.

Experimental

General techniques

All reactions were carried out under a nitrogen atmosphere using standard Schlenk techniques. Solvents were distilled under nitrogen from appropriate drying agents and degassed prior to use. Preparative thin-layer chromatography (TLC) was carried out on commercial Merck plates with a 0.25 mm layer of silica, or on 1 mm silica plates prepared at the University Chemical Laboratory, Cambridge. Column chromatography was performed on Kieselgel 60 (70–230 or 230–400 mesh). Products are given in order of decreasing $R_{\rm f}$ values.

The instrumentation used to obtain spectroscopic data has been described previously.²¹ Unless otherwise stated all reagents were obtained from commercial suppliers; Ph₂P(SCMe₃) was prepared by the literature method.¹¹

Syntheses of complexes

[Fe₃(μ₃-S)(μ-PPh₂)₂(μ-CO)(CO)₆] 1 and [{Fe₂(μ-PPh₂)-(CO)₆}₂(μ₄-S₂)] 2. A solution of [Fe(CO)₅] (1.0 ml, 7.60 mmol) and Ph₂P(SCMe₃) (2.00 g, 7.28 mmol) in toluene (50 ml) was added to a 100 ml Roth autoclave and pressurised with 5 atm of CO. The sealed system was stirred at 423 K for 20 h. After removal of the solvent under reduced pressure, the mixture was purified using preparative TLC with hexane–dichloromethane (10:1) as eluent. This gave in addition to decomposition products the orange crystalline [{Fe₂(μ-PPh₂)(CO)₆}₂(μ-S₂)] 2 (0.099 g, 3%) and green crystalline [Fe₃(μ₃-S)(μ-PPh₂)₂-(μ-CO)(CO)₆] 1 (0.576 g, 31%) complexes. NMR (CDCl₂): ¹³C (¹H composite pulse decoupled), δ 220.7[d, ${}^{2}J(PC)$ 12, CO], 218.9[d, ${}^{2}J(PC)$ 15, CO], 215.5[d, ²J(PC) 16, CO], 210.6[d, ²J(PC) 19, CO], 203.6[dd, ²J(PC) 35, 35, PPh₂CHC(CH₂OH)], 140.3[d, ²J(PC) 22, PPh₂-CHC(CH₂OH)S], 135–125[m, Ph, PPh₂CHC(CH₂OH)], 74.3[d, ²*J*(PC) 26, PPh₂CHC(*C*H₂OH)], 68.1[s, PPh₂CHC(*C*H₂OH)S] and 47.6[dd, ¹J(PC) 41, ³J(PC) 7 Hz, PPh₂CHC(CH₂OH)S]. FAB mass spectrum (5): m/z 756 (M^+) and $M^+ - nCO(n =$ 1-5).

Crystal structure determinations of complexes 2, 3c and 4a

For complexes **2** and **3c** X-ray intensity data were collected on a Siemens P4 four-circle diffractometer and for **4a** on a Phillips PW1100 four-circle diffractometer. Table 5 lists details of data collection, refinement and crystal data. Data were corrected for Lorentz and polarisation factors.

For all structures the metal positions were deduced from the Patterson method and subsequent Fourier-difference syntheses revealed the positions of the remaining non-hydrogen atoms. For 2 and 3c, refinements were performed using SHELXTL²² based on F^2 and for 4a with SHELX 76 based on F.²³ The phenyl rings in 3c and 4a were constrained to refine as rigid hexagons. The phenyl ring hydrogen atoms were placed in calculated positions with displacement parameters equal to $1.2U_{eq}$ of the parent carbon atoms for 2 and 3c, and those of 4a were fixed at 0.08 Å^2 . There were two independent molecules per equivalent position in the crystal structure of 4a. After initial refinement with isotropic displacement parameters,

empirical absorption corrections were applied to the data of 2, 3c and 4a.²⁴ Anisotropic displacement parameters were assigned in structures 2 and 3c to all non-hydrogen atoms and in 4a to only the iron, phosphorus, sulfur and carbonyl atoms.

The correct stereochemistry of the refined molecule depicted in Fig. 3 is confirmed by the Flack parameter of -0.01(3). Clearly, as complex 3c is racemic, equal numbers of both enantiomers will be present in the bulk sample. The racemic mixture of 4a also crystallises in a chiral space group $(P2_1)$ but in this case both enantiomers are present in the same crystal; molecules of opposing stereochemistry are paired in a chiral arrangement in the asymmetric unit. Equivalent bond lengths in the two molecules were constrained to be equal within an e.s.d. of 0.05 (Fe–Fe) or 0.01 Å (bonds involving other atoms). Inverting the chirality of the molecules made negligible difference to R.

CCDC reference number 186/1673.
