ABSTRACT

The disaccharides 2-*O*-Me- α -L-Fucp-(1 \rightarrow 2)- β -D-Galp-(1 \rightarrow OAllyl) **12**, α -L-Fucp-(1 \rightarrow 2)-4-*O*-Me- β -D-Galp-(1 \rightarrow OAllyl) **15**, and 2-*O*-Me- α -L-Fucp-(1 \rightarrow 2)-4-*O*-Me- β -D-Galp-(1 \rightarrow OAllyl) **18** have been synthesized. Glycosylation reactions were performed using ethyl 1-thiofucopyranosides as glycosyl donors and *N*-iodosuccinimide-triflic acid as the activating agent. The *O*-methylated disaccharides correspond to highly immunogenic *O*-glycan antigens occurring at the surface of *Toxocara canis* and *Toxocara cati* larvae.

INTRODUCTION

Toxocara canis and *Toxocara cati* are parasitic roundworms usually occurring in dogs and cats, which may cause severe infections in a human host affecting eyes, liver and the central nervous system.² The surface coat of the parasitic nematode larvae represents the major immunological challenge to the host immune system.³ In particular, glycoproteins being present in multiple copies at the outer layer elicit a strong immune response, are subsequently released from the surface and divert the immune attack from the mobile nematode. The structure of the excreted and secreted glycoproteins (TES antigens) from *Toxocara canis* investigated by MS analysis of alditol acetates revealed the presence of the trisaccharide backbone α -L-Fucp-(1 \rightarrow 2)- β -D-Galp-(1 \rightarrow 3)-D-GalpNAc.⁴ The fucose part has been found to be *O*-methylated at the 2-position. In addition, \sim 50% of the glycans

contained a 4-*O*-methyl group at the galactopyranosyl unit, which is also the prominent structure found in *T. cati* glycans. The anomeric configuration of the GalpNAc residue has yet to be elucidated. Monoclonal anti-carbohydrate antibodies which have been raised against the TES antigens bind to different sites within the larval parasite.⁵ For a detailed immunochemical characterization of those monoclonal antibodies, we have synthesized three potential carbohydrate ligands which are *O*-methylated either at position 2 of the fucopyranosyl moiety or at position 4 of the galactopyranosyl unit or at both positions. Herein we report on the synthesis of the corresponding disaccharide allyl glycosides, which may be converted into spacer-elongated derivatives to be coupled to proteins.⁶

RESULTS AND DISCUSSION

For the synthesis of the allyl galactopyranoside acceptor derivatives, the known⁷ allyl β -D-galactopyranoside **1** was reacted with anisaldehyde dimethyl acetal in the presence of *p*-toluenesulphonic acid in MeCN to give the crystalline 4,6-*O*-*p*-methoxybenzylidene derivative **2** in 81% yield.⁸ Regioselective protection of the 3-OH group was achieved in 77% yield by reaction of the 2,3-*O*-dibutylstannylene intermediate with *p*-methoxybenzyl chloride / tetra-*n*-butylammonium iodide⁹ to furnish the acceptor **3**.

For the subsequent introduction of the 4-*O*-methyl group, compound **3** was *O*-acetylated with acetic anhydride / pyridine to afford compound **4** in 92% yield. The ¹H NMR spectrum of **4** displayed a downfield shift for H-2 to 5.36 ppm, thereby confirming the structural assignment of the 3-*O*-*p*-methoxybenzyl substituent. Reductive ring opening of the benzylidene acetal¹⁰ using NaCNBH₃ / trifluoroacetic acid in DMF furnished the 6-*O*-*p*-methoxybenzyl ether derivative **5** in 70% yield and the 4-*O*-*p*-methoxybenzyl isomer in 20% yield. Methylation of **5** was performed with MeI / NaH in DMF to give compound **6** in 87% yield. Removal of the 2-*O*-acetyl group was accomplished by treatment of **6** with Bu₄NOH in aq 1,4-dioxane, which gave the 4-*O*-methyl-galactopyranoside acceptor **7** in 82% yield (Scheme 1).

For the synthesis of the α -L-Fucp-(1 \rightarrow 2)- β -D-Galp-(1 \rightarrow OAllyl) disaccharide¹¹ derivatives, *S*-ethyl β -L-fucopyranosides were used as glycosyl donors. They were synthesized by *O*-acetylation (of known precursors¹²) to give the 3,4-di-*O*-acetyl derivatives **8** and **9**, respectively. Coupling of the glycosyl donors with the galactopyranoside acceptor derivatives was carried out under iodonium ion activation of the thioglycoside using *N*-iodosuccinimide and trifluoromethanesulphonic acid at -20°C in dichloromethane-diethyl ether.¹³ Coupling of donor **9** with acceptor **3** gave the α -(1 \rightarrow 2)-linked disaccharide derivative **10** in 58% yield together with the β -(1 \rightarrow 2)-linked isomer (18%). The ¹H NMR spectrum of **10** showed a doublet for H-1' at 5.53 ppm with a coupling constant of 3.7 Hz. Similar reactions with the 4-*O*-methylated acceptor **7** and the thiofucopyranoside donors **8** and **9** proceeded with better anomeric selectivity to furnish disaccharide **13** in 83% yield (and 6% of the β -isomer) and the dimethylated disaccharide **16** in 88% yield

Scheme 1.

(and 11% of the β -isomer, respectively). Acid hydrolysis of the *p*-methoxybenzyl or *p*-methoxybenzylidene group of derivatives **10** and **13** with 90% aq TFA followed by *O*-acetylation afforded the penta-*O*-acetyl disaccharides **11** and **14** in 84% and 65% yield, respectively. The *p*-methoxybenzyl ether groups of compound **16** were cleaved by the action of ceric ammonium nitrate. Subsequent *O*-acetylation gave the dimethylated disaccharide **17** in 76% overall yield. Zemplén de-*O*-acetylation of the acetylated disaccharides and final purification furnished the disaccharides 2-*O*-Me- α -L-Fucp-(1 \rightarrow 2)- β -D-Galp-(1 \rightarrow OAllyl) **12**, α -L-Fucp-(1 \rightarrow 2)-4-*O*-Me- β -D-Galp-(1 \rightarrow OAllyl) **15** and 2-*O*-Me- α -L-Fucp-(1 \rightarrow 2)-4-*O*-Me- β -D-Galp-(1 \rightarrow OAllyl) **18** in 92%, 96% and 97% yield, respectively (Scheme 2).

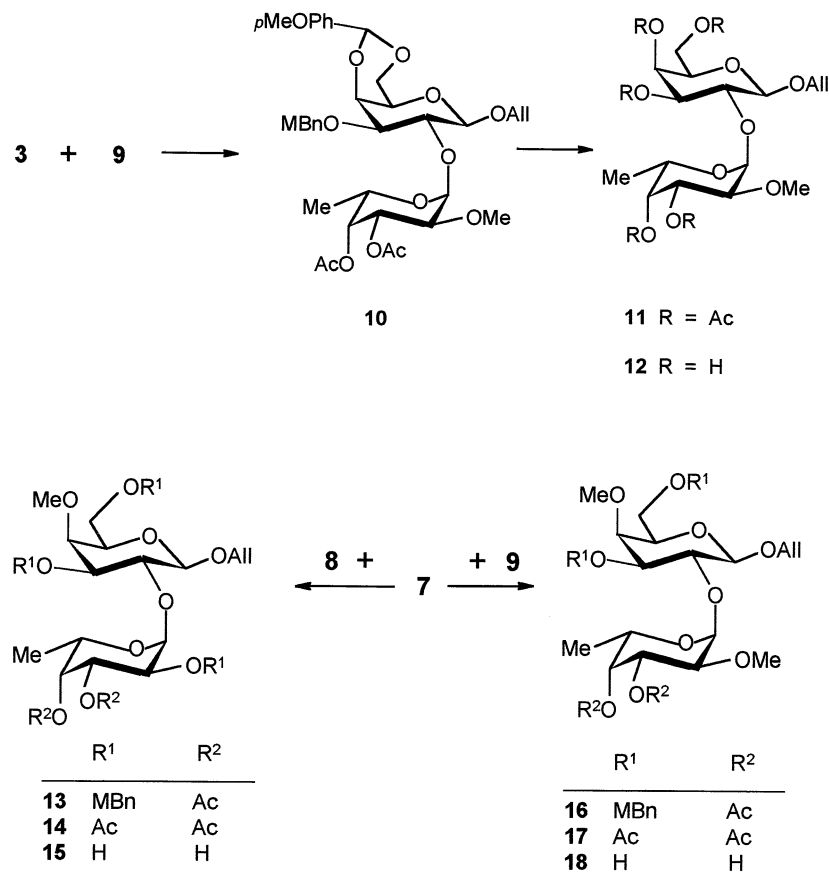

Structural assignments were confirmed by the ^{13}C NMR data (based on HMQC and HMBC spectra, Table 1) and compare favorably with data of related *O*-methylated oligosaccharides.¹⁴

The synthesis of the trisaccharides and immunochemical data derived from neoglycoconjugates will be published elsewhere.

EXPERIMENTAL

General methods. Melting points were determined with a Kofler hot stage and are uncorrected. Optical rotations were measured with a Perkin-Elmer 243 B polarimeter. ^1H NMR spectra were recorded with a Bruker DPX 300 instrument and tetramethylsilane or DSS as internal standards; coupling constants are first order. Homo- and heteronuclear 2D NMR spectroscopy was performed with Bruker standard software. Thin-layer chromatography was performed on Merck precoated plates (5 x 10 cm, layer thickness 0.25 mm, Silica Gel 60F₂₅₄); spots were detected by spraying with anisaldehyde-H₂SO₄ reagent. Column chromatography was per-

S-Ethyl 3,4-Di-*O*-acetyl-2-*O*-methyl-1-thio- β -L-fucopyranoside (9). A solution of *S*-ethyl 3,4-*O*-isopropylidene-2-*O*-methyl-1-thio- β -D-fucopyranoside (500 mg, 1.91 mmol) in CH_2Cl_2 (40 mL) was treated with 90% aq trifluoroacetic acid (1 mL) at rt for 2 h. Triethylamine (0.5 mL) was added, and the solvent was evaporated. The residue was dissolved in pyridine (20 mL) and stirred with a catalytic amount of 4-*N,N*-dimethylaminopyridine and acetic anhydride (3 mL) for 48 h at rt. Methanol (6 mL) was added, and the solution was concentrated. Purification of the residue on silica gel (C, 3:1 hexane/EtOAc) afforded **9** as a syrup. Yield:
