# Vapor-Liquid Equilibrium Data for the Ternary System Acetone–2-Propanol–Water and Corresponding Binaries from Total Pressure Measurements

RUBENS S. RAMALHO and JEAN F. DROLET<sup>1</sup>

Department of Chemical Engineering, Laval University, Quebec, Canada

Isothermal vapor-liquid equilibrium data were obtained by the total pressure method for the binaries acetone–2-propanol, acetone–water, and 2-propanol–water at 75° C. Ternary data were obtained, also at 75° C, for the system acetone–2-propanol– water. A numerical method was employed in all binary and ternary calculations.

The total pressure method for obtaining vapor-liquid equilibrium data consists in the determination of bubble point temperatures of mixtures of known compositions as functions of pressure. The main advantages of the method are elimination of the analysis of vapor and liquid phases at equilibrium, which usually introduces appreciable error in the results, and a considerable reduction of the time required to obtain the data.

In a previous paper (5), a numerical method for calculating vapor-liquid equilibrium data for binary and ternary systems, from total pressure measurements, was presented. This method has been used in performing the calculations needed in this investigation. This paper presents isothermal data at  $75^{\circ}$  C for the binary systems acetone-2-propanol, acetone-water, and 2-propanol-water, as well as ternary data, also at  $75^{\circ}$  C, for the system acetone-2-propanol-water.

### EXPERIMENTAL

The experimental apparatus was, with some minor modifications, that employed by Prengle and Palm (4). Three ebulliometers were operated concurrently at the same pressure, to speed up the collection of data. Detailed drawings of the equipment and operating procedure are available from the authors (1, 2). The probable uncertainties in each of the primary variables for this type of experimental determination are discussed by Prengle and Palm (4).

The temperatures were measured by platinum resistance thermometers, calibrated by the National Research Council of Canada. These thermometers are accurate to  $\pm 0.001^{\circ}$ C. However, because of small temperature fluctuations, the accuracy of the temperature measurements is estimated to be  $\pm 0.05^{\circ}$ C.

The pressures were measured by a mercury manometer. A cathetometer was employed for reading the height of the mercury column. Although a reading accurate to 0.1 mm is theoretically possible, small pressure fluctuations limit the accuracy of the measurement to  $\pm 1$  mm Hg.

obtained. Tables detailing intermediate calculated results are also available from the authors (2).

## TERNARY DATA FOR SYSTEM ACETONE-2-PROPANOL-WATER

The ternary system acetone-2-propanol-water is of interest, since it occurs in the process for making acetone by catalytic dehydrogenation of isopropyl alcohol. No data for this system had been previously reported in the literature.

For a systematic study of ternary combinations, a parameter, a, is defined as

$$a = \frac{x_2}{x_1 + x_2} = \text{constant} \tag{1}$$

Figure 1 illustrates the procedure followed to obtain the data. Each straight line (such as the one for a = 0.35), corresponds to a constant value of a. The experimental

measurements were conveniently taken along each line (a = 0.10, 0.20, 0.35, 0.50, 0.65, 0.80, and 0.90). The range of pressures involved was between 300 and 1500 mm Hg. Hg.

Because of the considerable amount of space required for presentation of all the data obtained, only a sample (for a = 0.35) is presented here. Similar data for the other

Figure 5. Activity coefficient for system acetone–2-propanol–water at  $75^{\circ}\,\text{C}$ 

Figure 6. Triangular diagram for system acetone–2-propanol– water at  $75^{\circ}\,\text{C}$ 

six values of a have been filed with the ASIS National Auxiliary Publications Service. The experimental data are presented in Table V, and the vapor-liquid data in Table VI. Figure 2 is a sample of the total pressure curves for a = 0.35. Similar sets of curves are available for the other values of a (2). Figures 3, 4, and 5 present the activity coefficient  $\gamma_1$ ,  $\gamma_2$ , and  $\gamma_3$  vs.  $x_1$ ,  $x_2$ , and  $x_3$  for the different values of parameter a.

The thermodynamic consistency of the ternary data was checked by the test of McDermott and Ellis (3), and the deviations are shown in Table 8 (filed with ASIS) for the case of a = 0.35. The data may be considered satisfactory, deviations being usually less than  $\pm 0.01$ . All the calculations in this work were performed by an IBM 360 (model 50).

Figure 6 is a triangular diagram, with vapor compositions plotted along the sides of the triangle, and showing curves corresponding to constant values of parameter a.

#### NOMENCLATURE

a = parameter for liquid compositions of ternary mixtures, Equation 1, dimensionless

$$B_{12}, B_{13}, B_{23}$$
  
 $C_{12}, C_{13}, C_{23}$ 

- $D_{12}, D_{13}, D_{14} =$  Redlich-Kister coefficients, dimensionless (Subscripts 1, 2, and 3 denote acetone, 2-propanol, and water, respectively, throughout this article)
  - C = Redlich-Kister coefficient for ternary system, dimensionless t = bubble point temperatures °C
  - t = bubble point temperatures, ° C
  - $x_1, x_2, x_3$  = mole fractions of components 1, 2, and 3, respectively, in liquid phase, for case of a ternary mixture, dimensionless
  - $x'_1, x'_2, x'_3$  = mole fractions of components in liquid phase, for case of a binary mixture, dimensionless
    - $y_i$  = mole fraction of more volatile component in vapor phase (i = 1, 2, 3), dimensionless

#### **Greek Letters**

- $\gamma_i$  = activity coefficient of component *i* in liquid phase (i = 1, 2, 3), dimensionless
- $\phi_i$  = correction coefficient for vapor phase, relative to component *i* (*i* = 1, 2, 3), dimensionless
  - = total pressure, mm Hg
