

# Electrical Conductances of Tetrabutylammonium Bromide, Sodium Tetrphenylborate, and Sodium Bromide in Methanol (1) + Water (2) Mixtures at (298.15, 308.15, and 318.15) K

Amritendu Chatterjee and Bijan Das\*

Department of Chemistry, North Bengal University, Darjeeling 734 013, India

The electrical conductances of the solutions of tetrabutylammonium bromide ( $\text{Bu}_4\text{NBr}$ ), sodium tetrphenylborate ( $\text{NaBPh}_4$ ), and sodium bromide ( $\text{NaBr}$ ) in methanol (1) + water (2) mixed solvent media containing 0.10, 0.20, and 0.30 volume fractions of methanol have been reported at (298.15, 308.15, and 318.15) K. The conductance data have been analyzed by the 1978 Fuoss conductance–concentration equation in terms of the limiting molar conductance ( $\Lambda^0$ ), the association constant ( $K_A$ ), and the association diameter ( $R$ ). The ionic contributions to the limiting molar conductance have been estimated using tetrabutylammonium tetrphenylborate ( $\text{Bu}_4\text{NBPh}_4$ ) as the “reference electrolyte”. All of these three electrolytes are found to exist as free ions in the present solvent mixtures within the temperature range (298.15 to 318.15) K. Besides the relative permittivity and the viscosity of the media, specific interactions of the ions with the solvent media have been found to play a profound influence on their mobilities. Although the association constants of the electrolytes do not vary significantly as a function of temperature, the limiting molar conductances of the electrolytes as well as the single-ion conductivity values increase appreciably with temperature.

## Introduction

Studies on the transport properties of electrolytes in different solvent media are of great importance to obtain information as to the solvation and association behavior of ions in solutions. Earlier, we have investigated<sup>1–7</sup> these properties for a wide variety of electrolytes in different solvents in great detail. The solvent properties such as the viscosity and the relative permittivity have also been taken into account in determining the extent of ionic association and the solute–solvent interactions that enabled many to interpret the unique structure of the solvent. The present paper reports the molar conductivities of tetrabutylammonium bromide ( $\text{Bu}_4\text{NBr}$ ), sodium tetrphenylborate ( $\text{NaBPh}_4$ ), and sodium bromide ( $\text{NaBr}$ ) in methanol (1) + water (2) mixtures at (298.15, 308.15, and 318.15) K in order to obtain precise temperature-dependent single-ion conductivities since such data are practically nonexistent in mixed solvent media.<sup>8,9</sup>

## Experimental Section

Methanol (Sisco, India, 99 % pure) was dried over molecular sieves and distilled fractionally. The middle fraction was collected and redistilled. The physical properties of the purified solvent were found to be in good agreement with the literature values.<sup>10</sup> Table 1 shows the comparison of the experimental values of density and viscosity of methanol with literature data.<sup>10</sup> Triply distilled water with a specific conductance of less than  $10^{-6} \text{ S}\cdot\text{cm}^{-1}$  at 298.15 K was used for the preparation of the mixed solvents. The densities and viscosities of methanol (1) + water (2) mixed solvents used in this study at (298.15, 308.15, and 318.15) K are reported in Table 1 along with those (at 298.15 K) obtained from the literature.<sup>11</sup> The relative permittivities of methanol (1) + water (2) mixtures were obtained by

regressing the relative permittivity data as a function of solvent composition from the literature<sup>12</sup> and are included in Table 1.

All of these salts were of Fluka purum or puriss grade. Tetrabutylammonium bromide ( $\text{Bu}_4\text{NBr}$ ) was purified by recrystallization from acetone, and the recrystallized salt was dried in vacuo at 333.15 K for 48 h. Sodium tetrphenylborate ( $\text{NaBPh}_4$ ) was recrystallized three times from acetone and then dried under vacuum at 353.15 K for 72 h. Sodium bromide ( $\text{NaBr}$ ) was dried in vacuo for 72 h immediately prior to use and was used without further purification.

Conductance measurements were carried out on a Pye-Unicam PW 9509 conductivity meter at a frequency of 2000 Hz using a dip-type cell of cell constant  $1.15 \text{ cm}^{-1}$  and having

an uncertainty of 0.01 %. The cell was calibrated by the method of Lind et al.<sup>13</sup> using aqueous potassium chloride solutions. The measurements were made in a water bath maintained within  $\pm 0.005$  K of the desired temperature. The details of the experimental procedure have been described earlier.<sup>14,15</sup> Solutions were prepared by mass for the conductance runs, the molalities being converted to molarities by the use of densities measured with an Ostwald–Sprengel-type pycnometer of about 25 cm<sup>3</sup> capacity. Several independent solutions were prepared, and runs were performed to ensure the reproducibility of the results. Due correction was made for the specific conductance of the solvent by subtracting the specific conductance of the relevant solvent medium from those of the salt solutions. The kinematic viscosities were measured using a suspended level Ubbelohde-type viscometer.

To avoid moisture pickup, all solutions were prepared in a dehumidified room with utmost care. In all cases, the experiments were performed at least in five replicates for each solution and at each temperature, and the results were averaged. The experimental uncertainties in density, viscosity, and conductivity were always within 0.01 %, 0.08 %, and 0.12 %, respectively.

## Results and Discussion

The measured molar conductances ( $\Lambda$ ) of electrolyte solutions as functions of molar concentration ( $c$ ) in methanol (1) + water (2) mixtures with volume fractions of 0.10, 0.20, and 0.30 of methanol at (298.15, 308.15, and 318.15) K are given in Table 2.

The conductance data have been analyzed by the 1978 Fuoss conductance–concentration equation.<sup>16,17</sup> For a given set of

conductivity values ( $c_j$ ,  $\Lambda_j$ ;  $j = 1, \dots, n$ ), three adjustable parameters—the limiting molar conductivity ( $\Lambda^0$ ), the association constant ( $K_A$ ), and the association diameter ( $R$ )—are derived from the following set of equations:

$$\Lambda = p[\Lambda^0(1 + RX + EL)] \quad (1)$$

$$p = 1 - \alpha(1 - \gamma) \quad (2)$$

$$\gamma = 1 - K_A c \gamma^2 f^2 \quad (3)$$

$$-\ln f = \frac{\beta k}{2(1 + kR)} \quad (4)$$

$$\beta = \frac{e^2}{\epsilon k_B T} \quad (5)$$

$$K_A = K_R(1 + K_S) \quad (6)$$

where  $RX$  is the relaxation field effect,  $EL$  is the electrophoretic countercurrent,  $\gamma$  is the fraction of unpaired ions, and  $\alpha$  is the fraction of contact pairs.  $K_A$  is the overall pairing constant evaluated from the association constants of contact pairs,  $K_S$ , of solvent-separated pairs,  $K_R$ .  $\epsilon$  is the relative permittivity of the solvent,  $e$  is the electronic charge,  $k_B$  is the Boltzmann constant,  $k^{-1}$  is the radius of the ion atmosphere,  $c$  is the molarity of the solution,  $f$  is the activity coefficient,  $T$  is the temperature in absolute scale, and  $\beta$  is twice the Bjerrum distance. The computations were performed on a computer using the program as suggested by Fuoss. The initial  $\Lambda^0$  values for the iteration procedure were obtained from Shedlovsky extrapolation<sup>18</sup> of the data. Input for the program is the set ( $c_j$ ,  $\Lambda_j$ ;  $j = 1, \dots, n$ ),  $n$ ,  $\epsilon$ ,  $\eta$ ,  $T$ , initial value of  $\Lambda^0$ , and an instruction to cover a preselected range of  $R$  values.

In practice, calculations are made by finding the values of  $\Lambda^0$  and  $\alpha$ , which minimize the standard deviation,  $\sigma$ :

$$\sigma = \left[ \sum [\Lambda_j(\text{calcd}) - \Lambda_j(\text{obsd})]^2 / (n - 2) \right]^{1/2} \quad (7)$$

for a sequence of  $R$  values and then plotting  $\sigma$  against  $R$ ; the best-fit  $R$  corresponds to the minimum in  $\sigma$  versus  $R$  curve. However, for the salts investigated here, since a preliminary scan using incremental  $R$  values from 4 to 20 produced no significant minima in the  $\sigma$  versus  $R$  curves, the  $R$  value was assumed to be  $R = a + d$ , where  $a$  is the sum of the ionic crystallographic radii and  $d$  is given by

$$d = 1.183(M/\rho_0)^{1/3} \quad (8)$$

where  $M$  is the molecular weight of the solvent and  $\rho_0$  is its density. The values of  $\Lambda^0$ ,  $K_A$ , and  $R$  obtained by this procedure are reported in Table 3.

To investigate the specific behavior of the individual ions comprising these electrolytes, it is necessary to split the limiting molar electrolyte conductances into their ionic components. The limiting ionic conductivities have been evaluated from the division of the  $\Lambda^0$  values of  $\text{Bu}_4\text{NBPh}_4$  using the following relationship:

$$\lambda^0(\text{Bu}_4\text{N}^+) = 0.517\Lambda^0(\text{Bu}_4\text{NPh}_4\text{B}) \quad (9)$$

as described in the literature.<sup>19,20</sup>

The limiting molar conductances of  $\text{NaBr}$  in some selected methanol (1) + water (2) mixtures at 298.15 K have also been reported by Zhang et al.<sup>11</sup> They analyzed their data with the

$$^a \sigma/\% = 100\sigma/\Lambda^0.$$

Fuoss–Onsager equation. Consequently, a direct comparison is not possible.

The limiting molar conductivity ( $\Lambda^0$ ) of the “reference electrolyte”  $\text{Bu}_4\text{NBPh}_4$  was obtained by considering the Kohlrausch rule that allows the calculation of the  $\Lambda^0$  value for a given electrolyte by the appropriate combination of others. The  $\Lambda^0$  values of  $\text{Bu}_4\text{NBr}$ ,  $\text{NaBPh}_4$ , and  $\text{NaBr}$  obtained in the present solvent media have been used to obtain the  $\Lambda^0$  value of  $\text{Bu}_4\text{NBPh}_4$  through the following equation:

$$\Lambda^0(\text{Bu}_4\text{NBPh}_4) = \Lambda^0(\text{Bu}_4\text{NBr}) + \Lambda^0(\text{NaPh}_4\text{B}) - \Lambda^0(\text{NaBr}) \quad (10)$$

The limiting ionic conductances calculated from the above equations are recorded in Table 4.

The association constants ( $K_A$ ) listed in Table 3 for all these systems are practically negligible (i.e.,  $K_A < 10$ ). So, the numerical values of  $K_A$  should not be taken seriously.<sup>21</sup> One can only conclude that all of these three electrolytes exist as free ions in the present methanol–water solvent mixtures within the temperature range of (298.15 to 318.15) K. This is expected because the relative permittivities of the solvent mixtures are

**Table 4. Limiting Ionic Conductances in Methanol (1) + Water (2) Mixtures Containing 0.10, 0.20, and 0.30 Volume Fractions of Methanol at (298.15, 308.15, and 318.15) K**

T/K	$\lambda_{\pm}^0/S \cdot \text{cm}^2 \cdot \text{mol}^{-1}$			
	Na <sup>+</sup>	Bu <sub>4</sub> N <sup>+</sup>	Br <sup>-</sup>	Ph <sub>4</sub> B <sup>-</sup>
		$\phi_1 = 0.10$		
298.15	50.66	17.36	63.80	16.21
308.15	58.12	18.54	76.76	17.33
318.15	71.04	22.29	92.46	20.82
		$\phi_1 = 0.20$		
298.15	41.14	12.85	52.71	12.00
308.15	53.32	14.99	64.88	14.01
318.15	69.65	16.62	83.57	15.53
		$\phi_1 = 0.30$		
298.15	34.45	10.72	49.22	10.01
308.15	49.76	14.26	56.79	13.32
318.15	64.06	15.10	77.98	14.11

fairly high ( $66.75 \leq \epsilon \leq 76.78$ ), thus promoting dissociation of electrolytes.

In all the mixed solvent media, the limiting ionic equivalent conductances decrease in the order:  $\lambda_{\text{Br}^-}^0 > \lambda_{\text{Na}^+}^0 > \lambda_{\text{Bu}_4\text{N}^+}^0 > \lambda_{\text{Ph}_4\text{B}^-}^0$  at each temperature, indicating that the sizes of these ions as they exist in solutions follow the order:  $\text{Br}^- < \text{Na}^+ < \text{Bu}_4\text{N}^+ < \text{Ph}_4\text{B}^-$ . It is also observed that the limiting ionic equivalent conductances of all the ions decrease in going from 0.10 volume fraction of methanol to 0.30 volume fraction of methanol in the mixture at all temperatures investigated.

The limiting equivalent conductances of the electrolytes as well as the single-ion conductivity values increase appreciably with temperature. The effect of temperature on  $\lambda_{\text{Na}^+}^0$  and  $\lambda_{\text{Br}^-}^0$  ions is more pronounced as compared to that as  $\lambda_{\text{Bu}_4\text{N}^+}^0$  and  $\lambda_{\text{Ph}_4\text{B}^-}^0$  in the present mixed solvent media.
