ABSTRACT: The enthalpies of solution ($\Delta_{sol}H$) of carbon dioxide (CO₂) in two aqueous solutions (w = 0.1500 and w = 0.3000) of monoethanolamine (MEA) have been measured at two temperatures (322.5 K and 372.9 K) and pressures up to 5 MPa. Measurements were carried out by a flow calorimetric technique using a custom-made flow-mixing unit combined with a SETARAM C-80 isothermal differential heat-flux calorimeter. Enthalpies of solution of CO₂ ($\Delta_{sol}H$) have been obtained as function of loading α (moles CO₂/mol amine). Solubility data of the gas into the different absorbent (s) were derived from the enthalpic data.

1. INTRODUCTION

The capture of carbon dioxide from postcombustion emission is one of the challenges for reducing the release of greenhouse gases into the atmosphere. Aqueous amine solutions are wellknown to be efficient chemical solvents for the industrial capture of CO₂. Gas capture combines physical dissolution and subsequent reaction of CO₂ into the absorbent solution. The acidbase reaction between the carbon dioxide and the amine is reversible, making it possible to separate the gas from the absorbent solution in a cyclic process. The purpose of actual research carried out on CO2 capture is the reduction of the energy cost of CO₂ removal in the amine washing process. To design a new industrial process for gas treating operations, the development of better theoretical models describing the $\{CO_2 +$ amine + H_2O } systems is required. The existing models¹⁻⁹ are based on temperature-dependent liquid-vapor equilibria data from which the enthalpy of solution of CO₂ was derived.^{4,7-9} Although gas solubility data as a function of temperature, amine composition, and partial pressure of CO_2 are available in the literature, ^{10–26} only a few experimental enthalpy studies have been published^{22,27,28} for the system { CO_2 + monoethanolamine $(MEA) + H_2O$. A literature review for both solubility data and enthalpy of solution of CO₂ is reported in Tables 1 and 2. To develop thermodynamic models able to describe the {CO₂ + MEA + H_2O } system we decided to extend the existing enthalpy data.^{22,27,28'} In addition, the new proposed set of data makes it possible to investigate the amine composition effect on the enthalpy of solution.

In this paper, we report a new set of experimental data on the enthalpy of solution for the system {CO₂ + MEA + H₂O}. Measurements were performed for two aqueous amine solutions ($w = 0.1500 \pm 0.0001$ and $w = 0.3000 \pm 0.0001$) at temperatures of 322.5 K and 372.9 K and pressures from 0.5 MPa to 5 MPa for CO₂ loadings up to the saturation of the absorbent solution. The measurements were carried out using a custom-made mixing cell developed for an isothermal differential heat flux calorimeter, the

Setaram C-80.²⁹ Solubilities of the gas into the different absorbents (s) at the same temperature, pressure, and amine weight fraction were deduced from the experimental enthalpic data.

2. EXPERIMENTAL SECTION

2.1. Experimental Arrangement. The calorimetric technique was similar to the one used previously to study the dissolution of CO₂ in aqueous solutions of 2-amino-2-methyl-1-propanol $(AMP)^{30}$ and *N*-methyl-diethanolamine (MDEA).^{31,32} The heat of absorption of CO₂ in aqueous solution of amine was measured using a custom-made flow-mixing cell adapted to a Setaram C-80 heat conduction differential calorimeter. This unit was housed in the calorimetric block, where the heat effect during the absorption of the gas into the aqueous solution of amine was detected by thermopiles. The overall experimental arrangement is depicted in Figure 1. The two fluids, CO₂ and aqueous amine solution, were injected into the mixing unit supplied by two ISCO model 100 DM high-pressure syringe pumps. The syringe pumps were regulated at a constant temperature of 298.15 K, using water batch, to maintain a constant mass flow rate. The flow line was made out of stainless steel tubing of 1.6 mm outer diameter (o.d.) and 1.0 mm inner diameter (i.d.). The system pressure was maintained constant to 0.02 MPa using a Circle Seal backpressure regulator placed at the end of the flow line. The pressure was measured by three electronic Keller pressure transducers connected to pressure indicators WEST 8010 with an accuracy of 0.25 % of the full scale. The pressure gauges were located at the outlets of the acid gas and aqueous phase pumps and between the mixing cell and the backpressure regulator. The temperature of the injected fluids was adjusted to the working temperature of the calorimeter before entering the mixing cell using four preheaters:

two external to the calorimeter and two inside it. The two external heaters were located just above the calorimetric block. The temperature of the calorimeter was set up and controlled within 0.01 K using a Setaram G11 electronic control device.

2.2. The Mixing Cell. The design of the mixing cell (Figure 2) is the same as that described by Koschel et al.³³ However, when the cell, with its stainless steel tubing, was used for the study of acid gases, it was found to corrode.³⁴ The cell was thus rebuilt in Hastelloy C22. The "T" connection in the upper part of the mixing unit, used by Koschel et al.,³³ was also removed. Instead, the CO₂ and the aqueous solution were injected through by two Hastelloy 1/16" tubing (1.6 mm o.d.), and contacted one another in a small chamber at the bottom of the cell, shown as "M" in Figure 2, where the two input tubes and a 2.8 m mixing chamber were silver-soldered together. The quantitative mixing occurs in this 2.8 m long mixing chamber, which consisted of Hastelloy C22 1/16″ tubing, coiled in good thermal contact with the inner wall of the confinement cylinder (18.7 mm i.d., 80 mm height).

2.3. The Preheaters. The preheaters are counter-current heat exchangers, shown in Figure 3. The two external heat exchangers (Figure 3a) consisted of a copper cylinder with the tubing coiled on its outer surface. The two internal heat exchangers (made also of copper, Figure 3b) were located inside the calorimeter block hole housing the mixing cell. They used the same Hastelloy tubing, tightly fitted in grooves inside the cylindrical

preheater cylinder. Both internal and external preheaters were thermoregulated by heating cartridges and a platinum resistance thermometer connected to a PID controller. The temperatures of the two external and the first internal preheaters were maintained constant to \pm 0.1 K by means of RKC CB 100 regulators. The second internal preheater was connected to a PID controller from Fluke Hart Scientific model 2200 that controls the temperature with stability to \pm 0.01 K.

2.4. Operating Procedure. The experiments were designed to measure the enthalpy of mixing between the two fluids (gas and aqueous solution) at constant temperature and pressure as a function of the CO₂ loadings, α (moles CO₂/mol amine). In our case, this enthalpy of mixing characterized the dissolution of the carbon dioxide into the amine solution and was defined as the enthalpy of solution of CO₂ in the aqueous solution of amine. This enthalpy of solution has also been called the enthalpy of absorption or heat of absorption by other authors.^{7,27,35} The loading was determined by the total molar flow-rate of CO₂ \dot{n}_{CO_2} divided by the total molar flow-rate of amine (eq 1).

$$\alpha = \frac{\dot{n}_{\rm CO_2}}{\dot{n}_{\rm amine}} \tag{1}$$

Typically the flow rates varied from 0.1 mL·min⁻¹ to 2 mL·min⁻¹ and 0.04 mL·min⁻¹ to 0.4 mL·min⁻¹ for CO₂ and the aqueous phase, respectively, with a relative uncertainty of 0.3 %. The molar flow rates were calculated from the pump flow rates using the densities, mass composition (for the aqueous amine solution), and molar mass of the fluids. The densities of aqueous MEA solutions were measured at 298.5 K (the regulation temperature of the syringe pump) as a function of the pressure using an Anton Paar densimeter DMA 512 (P model) following the Jacquemin procedure;³⁶ values are reported in Table 3. The densities of CO₂ were calculated from ALLPROPS software.³⁷

The enthalpy was directly obtained from the thermopile signal $S(\mu V)$ of the calorimeter and the molar flow-rate $\dot{n} (\text{mol} \cdot \text{s}^{-1})$ of the solution. Before measuring the thermopile signal $S_{\rm M} (\mu V)$

Figure 1. Schematic diagram of the flow-mixing calorimeter.

Figure 2. Schematic diagram of the mixing cell.

during the mixing process, a baseline signal $S_{\rm BL}$ (μ V) was recorded with only the aqueous phase flowing through the calorimeter. The baseline signal was kept close to zero by adjusting the thermoregulation of the entering fluids. The signal was recorded for 20 min before the gas injection. The heat effect due to the gas dissolution corresponded to a thermopile signal ($S_{\rm M} - S_{\rm BL}$) ranging from 4 mV to 16 mV and typically had stability better than \pm 0.1 mV. This signal was recorded for at least 30 min, and then the baseline signal was again recorded for 20 min.

Enthalpies of solution $(\Delta_{sol}H)$ expressed as kJ·mol⁻¹ of CO₂ or kJ·mol⁻¹ of amine, were derived from the calorimetric signal using the molar flow rate of CO₂ or the molar flow rate of amine, respectively. The enthalpy of solution $(\Delta_{sol}H)$ was calculated from eq 2 using the thermopile signals $S_{\rm M}$ and $S_{\rm BL}$ (μ V) and the

molar flow rate $\dot{n} \pmod{\cdot s^{-1}}$ of the gas $(\Delta_{sol}H/kJ \cdot mol^{-1} \text{ of } CO_2)$ or the molar flow rate of amine $(\Delta_{sol}H/kJ \cdot mol^{-1} \text{ of amine})$

$$\Delta_{\rm sol}H = \frac{\Delta_{\rm signal}}{E \cdot \dot{n}} \tag{2}$$

where Δ signal represented the difference in the thermopile signal during the mixing process and the baseline (only when the aqueous amine solution was running through the mixing flow calorimeter). The molar flow rate \dot{n} was derived from the volumetric pump flow rates, the densities, and the amine concentration. The thermopile sensitivity $E (\mu V \cdot m W^{-1})$ used to convert the thermopile signal to heat power was given by the constructor as a function of the temperature. However, it could

have slightly changed with time; it was thus recalibrated measuring the heat of mixing of a binary system whose enthalpy of mixing is well-known. For the purpose we chose the reference $\{C_2H_5OH + H_2O\}$ system, using the enthalpy data provided by Ott et al.^{38,39} The difference between the thermopile sensitivity obtained by chemical calibration and that reported by SETARAM was typically less than 5 %.

The experimental uncertainty on the enthalpy of solution, $\delta(\Delta_{sol}H)$, was determined as a statistical estimate from the expected error in E, uncertainties on the molar flow rate, and the heat power based on eq 2. The uncertainty on the molar flow rates depends on the uncertainty on the volumetric flow rates of the pumps and the accuracy of the fluid densities. For the gas it was estimated to be smaller than 0.3 % at 5 MPa and 3 % at 0.2 MPa, and for the aqueous amine solution it was estimated to be smaller than 1 %. The error on the heat power is related to the accuracy of the thermopile sensitivity E of the calorimeter, estimated to 2 %, and to the fluctuations of the calorimetric signal. The uncertainty in the difference in the thermopile signal during the mixing process and the baseline was between 1 % and 3 % and can reach 5 % for the smallest measured heat effects. Calculations for the determination of the experimental uncertainties are described in detail elsewhere.⁴⁰

2.5. Chemicals and Materials. MEA was obtained from Fluka Organics with a purity > 99 % and was used without further purification. Carbon dioxide (purity of 99.998 %) was obtained from Saga. Water was distilled and degassed before used (resistivity 18.2 M Ω ·cm). Aqueous solutions were prepared and kept under nitrogen atmosphere by mass with an uncertainty in the mass fraction estimated as less than $\pm 10^{-4}$. Aqueous solutions were stored in glass bottle in an opaque cabinet to prevent any photodegradation.

3. RESULTS AND DISCUSSION

3.1. Enthalpy Data. The enthalpy of solution of CO_2 in the aqueous amine (MEA) solutions (w = 0.1500 and 0.3000) was measured at 322.5 K and 372.9 K at pressures from 0.5 MPa to 5 MPa. The experimental data were obtained for different gas—solvent flow rate ratios; they are presented in Tables 4 to 7. The uncertainties in the enthalpy were determined as indicated above. Experimental enthalpies are plotted versus loading α (moles of CO_2 /mol of amine) in Figures 4 and 5; large exothermic effects were observed at both temperatures. The graphs where the enthalpy (/kJ·mol⁻¹ of amine) is plotted versus the loading show up typically two domains that correspond:

- (i) to a total dissolution of CO₂ injected (unsaturated solution);
- (ii) to a partial dissolution of CO_2 injected (saturated solution).

When the enthalpy of solution $\Delta_{sol}H$ is expressed in kJ·mol⁻¹ of CO₂ (Figure 4) the graphs exhibit plateaus for the lowest loadings up to 0.5, and then the exothermic effect decreases as the loading increases. At the lowest loadings (Figure 4), the energetic effect per mole of gas seemed to be constant, within the experimental uncertainty, and independent of CO₂ loading. This behavior was also observed and reported by other authors.^{4,35}

The border between unsaturated and saturated absorbent is not obvious when the enthalpy is expressed per mole of gas. The absorption of CO_2 in aqueous solutions of the primary (MEA) amine is a combination of chemical reactions and physical dissolution. Chemical absorption of CO_2 in aqueous solutions

$$co_2 + 2C_2H_5NH_2 \rightleftharpoons C_2H_5NHCOO^- + C_2H_5N^+H_3$$
 (3)

A two-step chemical mechanism (eqs 4 and 5) with a zwitterion formation was proposed by Caplow⁴¹ to explain eq 3.

$$CO_2 + C_2H_5NH_2 \rightleftharpoons C_2H_5N^+H_2COO^-$$
(4)

$$C_{2}H_{5}N^{+}H_{2}COO^{-} + C_{2}H_{5}NH_{2} \rightleftharpoons$$

$$C_{2}H_{5}NHCOO^{-} + C_{2}H_{5}NH_{3}^{+} \qquad (5)$$

The solubility of the gas into the solution is thus limited by stoichiometry to a maximum loading $\alpha = 0.5$ mol CO₂/mol amine. However, due to possible carbamate hydrolysis, the loading may exceed 0.5 when increasing CO₂ pressure.⁴²

$$C_2H_5NHCOO^- + H_2O \rightleftharpoons C_2H_5NH_2 + HCO_3^-$$
(6)

In that case the dissolution process is not controlled anymore by the carmate formation but by the carbon dioxide, which reacts with the amine to form a carbonate. The solubility can thus be extend up to $\alpha = 1.0$ mol CO₂/mol amine. The change of energetic behavior observed around $\alpha = 0.5$ seems to be

associated to the change of the governance for the chemical mechanisms involved in the $\rm CO_2$ dissolution.

A discussion of the effects of temperature, pressure, and absorbent composition on the dissolution of carbon dioxide will be carried out by a comparison of enthalpies of solution when they were found to remain constant (i.e., average enthalpy values $\Delta_{sol}H^{av}$ expressed in kJ·mol⁻¹ of CO₂, estimated on the plateaus). Numerical values are reported in Table 8.

The enthalpy of solution $\Delta_{sol}H^{av}$ was estimated to be 88 ± 2 kJ·mol⁻¹ of CO₂ and 89 ± 4 kJ·mol⁻¹ of CO₂ for w = 0.1500 and w = 0.3000, respectively. The pressure and temperature effects on the enthalpy of solution of CO₂ in MEA solutions were not found to be significant regarding experimental uncertainty. However the enthalpy decreased drastically at p = 3.08 MPa and at p = 5.13 MPa for dissolution in a solution of mass composition w = 0.1500 and w = 0.3000, respectively. The behavior was attributed to technical difficulties when experiments were carried out for low gas loading. In these conditions of elevated pressures the difference in volume flow rates of carbon dioxide and absorbent solution is important, leading to problems of mixing. This difference increases with the volumetric mass of CO₂, that is, with pressure or when decreasing amine composition.

Figure 4. Enthalpy of solution $(-\Delta_{sol}H/(kJ \cdot mol^{-1} \text{ of } CO_2))$ versus CO₂ loading for the aqueous solution of MEA: \Box , 0.5 MPa; \diamond , 1.0 MPa; \bigcirc , 5.0 MPa.

Considering the small temperature, pressure, and absorbent composition dependency on the dissolution of carbon dioxide into aqueous MEA solution (under $\alpha = 0.5$ mol CO₂/mol amine), we decided to test a simplified thermodynamic model⁴³ that does not take into account the effects mentioned above for estimating the enthalpy of solution. In this model,⁴³ the reaction of CO₂ with the amine is represented by a single equilibrium equation (eq 7):

$$C_2H_5N^+H_3 + HCO_3^- \rightleftharpoons C_2H_5NH_2 + CO_2 + H_2O \quad (7)$$

The single equilibrium constant K_{CO_2} associated to eq 7 is defined by eq 8:

$$K_{\rm CO_2} = p_{\rm CO_2} \left(\frac{1 - \alpha}{\alpha \cdot x_{\rm CO_2}} \right) \tag{8}$$

where p_{CO_2} is the partial pressure of CO₂ and x_{CO_2} its molar fraction.

The equilibrium constant is then fitted to eq 9:

$$\ln(K_{\rm CO_2}/\rm kPa) = A + \frac{B}{T} + C(\alpha \cdot \mathring{x_{\rm MEA}}) + D\sqrt{\alpha \cdot \mathring{x_{\rm MEA}}}$$
(9)

where x_{MEA}° is the gas free amine mole fraction and *A*, *B*, *C*, and *D* are fitting parameters.

The enthalpy of reaction (eq 7) is derived using the van't Hoff equation that leads also to the opposite of the enthalpy of solution (eq 10):

$$\Delta_{\rm r} H = \left(\frac{\partial \ln K_{\rm CO_2}}{\partial T}\right) = -BR = -\Delta_{\rm sol} H \tag{10}$$

Parameters A, B, C, and D (Table 9) were obtained using solubility data selected from Table 1, gathering 99 equilibrium points. The experimental equilibrium constant $K_{CO_2}^{exp}$ was

for the regression, as it seems the enthalpy would remain constant in that domain (see discussion above). The enthalpy of solution estimated from this model⁴³ is supposed to be independent in the limits of the selected literature domain: temperatures from 313 K to 423 K, amine compositions between w = 0.015 and w = 0.030 wt %, and pressures between $2 \cdot 10^{-6}$ MPa to 0.56 MPa. Within these approximations we calculated an enthalpy of solution, $\Delta_{sol}H = -88 \pm 2 \text{ kJ} \cdot \text{mol}^{-1}$ of CO₂, in close agreement with our experimental average enthalpies $\Delta_{sol}H^{av}$ regarding the experimental uncertainty.

3.2. Solubility Data. The calorimetric data were used for an indirect determination of the solubility limits of CO_2 in the aqueous amine solutions. Numerical values were graphically determined from Figure 5; they are reported in Table 10 for the different conditions of temperature, pressure, and composition investigated in this study. Up to the saturation of the MEA solution the enthalpy expressed per mole of amine increases with loading until it reaches a plateau. The plateau indicates that no more carbon dioxide can be dissolved into the solution; the solution is saturated (two-phase region). The solubility limit corresponds thus to the point where the plateau is reached.

The experimental uncertainty depends on the identification precision of the first point of the plateau, and on the basis fo the

Figure 7. Solubility of CO₂ in MEA solutions vs total pressure. (a) $w_{\text{MEA}} = 0.15$, \Box , this work, T = 322.5 K; \bigcirc , this work, T = 372.9 K; \diamondsuit , Shen and Li,¹⁷ T = 313 K. (b) $w_{\text{MEA}} = 0.30$, \blacksquare , this work, T = 322.5 K; \bigoplus , this work, T = 322.9 K; \clubsuit , Shen and Li,¹⁷ T = 313 K; \blacktriangle , Shen and Li,¹⁷ T = 313 K; \bigstar , Shen and Li,¹⁷ T = 373 K.

reproducibility of the measurements and possibility of systematic errors affecting the enthalpy of solution or the flow rates reliability of the pumps, it is expected that this method allows a determination of the solubility limit within 5 % and 9 %.

Limits of solubility of CO_2 in the aqueous solutions of MEA were plotted versus the equilibrium total pressure p on a pressure—log scale in Figure 7 as well as literature values from Shen and Li.¹⁷ A good agreement characterized by a devia-555tion smaller than 5 % with their data on the solubility was observed.

The general tendency is a decrease of the CO_2 solubility (expressed in mol of CO_2 per mol of MEA) in aqueous MEA solutions with the composition of the absorbent (Table 10); this trend agrees with the other studies found in the literature. Indeed when increasing the amine concentration, the number of molecules of water necessary to solvate ions in solution also increases. Consequently, the number of molecules of water available to solvate CO_2 decreases. One can also notice that, in the same conditions of composition and pressure, an augmentation of the temperature leads to a decrease of the solubility as the basicity of the amine also decreases.

As a final remark, the good consistency observed between solubility limits from this work and the literature, measured using methods specifically designed for solubility work, indicated that the mixture of CO_2 -absorbent solution occurred properly during the calorimetric experiments. However, it was pointed out that our experimental technique was limited to reasonable differences of volume flow rates between gas and solution to prevent any mixing issue.

4. CONCLUSION

In this paper we provided new experimental enthalpy of solution data for the system $\{CO_2 + MEA + H_2O\}$. The solubility data derived from our enthalpy data were found to be consistent with the direct phase equilibria measurements from the literature within the estimated experimental uncertainty.

The enthalpy of solution, $\Delta_{sol}H$ (/kJ·mol⁻¹ of CO₂) was found to be constant at low CO₂ loading within experimental uncertainty. In this domain an average enthalpy of solution, $\Delta_{sol}H^{av}$, was estimated for conditions of pressure and amine composition investigated. These values were used to discuss pressure, temperature, and absorbent composition effects on the enthalpy of solution. The enthalpies of solution of carbon dioxide in aqueous solutions of MEA were observed to be independent of pressure within experimental uncertainty. However, the enthalpy obtained at the highest pressures and low loadings, above 2 MPa, seemed to be experimentally underestimated. This could be due to CO_2 -absorbent mixing difficulties. No significant temperature or composition effect was observed.

A simplified thermodynamic model⁴³ that does not take into account pressure, temperature, and absorbent composition effects was used to estimate the enthalpy of solution. Within these approximations the calculated enthalpy of solution was found to be quite close to our experimental average enthalpies, $\Delta_{sol}H^{av}$. However, this simplified thermodynamic model⁴³ was not able to describe the enthalpy of solution for loadings above $\alpha = 0.5 \text{ mol } CO_2/\text{mol amine}$, where the dissolution process is not controlled anymore by the carbamate formation but by the carbon dioxide, which reacts with the amine to form a carbonate. In that case it would be helpful to use a rigorous thermodynamic model⁸ to describe the change of energetic behavior observed around $\alpha = 0.5$ where it seems to have a change of the governance for the chemical mechanisms involved in the CO₂ dissolution. For this purpose, the experimental enthalpies provided in this work could be used as consistent experimental data to develop such theoretical thermodynamic models and design new industrial process for gas treating operations.
