# A LEAD(II) COMPLEX WITH ETHYLENEDIAMINE CONTAINING A BRIDGING ACETATE GROUP: DIRECT SYNTHESIS AND CRYSTAL STRUCTURE 

VALERY POLYAKOV AND VLADIMIR KOKOZAY*<br>Department of Inorganic Chemistry, Kiev University, Vladimirskaya. 64, Kiev 252017, Ukraine

(Received November 16, 1993)

#### Abstract

A dircet method of obtaining $\mathrm{PbEnAc}\left(\mathrm{Ac}=\mathrm{CH}_{3} \mathrm{COO} \mathrm{En}=\right.$ ethylenediamine) is reported. The crystal structure of the compound was determined by X-ray techniques. $\mathrm{PbEnAc}_{2}$ is monoclinic, space group $P 2_{1} / c$, with cell parameters $a=5.532(1), b=24.185(5), c=7.630(1) \AA, V=1010.22(47) \AA^{3}, Z=$ 4; calculated density is $2.534 \mathrm{~g} / \mathrm{cm}^{3}$. Two different types of acetate group were found. The first is cyclic and the second is bridging. The bridging acetate group links neighboring lead atoms into polymeric chains.

KEYWORDS: lead (II), X-ray structure, ethylenediamine, acetate

## INTRODUCTION

Diffusion through the product forming at the reaction surface largely influences lead oxide reactions with ammonium salts solutions. ${ }^{1}$ Shortage of ligand diffusing to the reaction surface can be one of the reasons for ethylenediamine bridging in the compound $\mathrm{PbEn}_{2} \mathrm{Br}_{2}$, obtained by direct synthesis. ${ }^{2}$ While continuing development of direct synthesis methods with metal oxides, we have prepared and investigated a lead(II) complex with ethylenediamine.

## EXPERIMENTAL

The preparation of initial compounds, methods of synthesis and investigation of products are similar to those reported ${ }^{3}$. For the preparation of $\mathrm{PbEnAc}_{2}$, the following method was used. Some $2.23 \mathrm{~g}(0.01 \mathrm{~mol})$ of $\mathrm{PbO}, 1.54 \mathrm{~g}(0.02 \mathrm{~mol})$ of $\mathrm{NH}_{4} \mathrm{Ac}, 20 \mathrm{~cm}^{3}$ of dimethylsulfoxide (DMSO) and $1.34 \mathrm{~cm}^{3}(0.02 \mathrm{~mol})$ of ethylenediamine (En) were placed in a flask and the mixture was stirred for one hour at $50-60^{\circ} \mathrm{C}$. The resulting colourless solution was allowed to stand at room temperature. This resulted in crystals separating from the solution. These were filtered, washed with dry isopropanol, and dried in vacuo at room temperature

[^0](yield: $2.85 \mathrm{~g}(74 \%)$ ). Calcd. for $\mathrm{PbEnAc}_{2}$ : $\mathrm{Pb}, 53.77$; N, 7.27; C, 18.70 ; H, 3.66\%. Found: Pb, 53,0; N, 7.1; C, 18.7; H, 3.6\%.

It should be noted that variation of initial $\mathrm{PbO}: \mathrm{En} \mathrm{mol}$ ratios in the range $1: 1-$ 3 does not influence complex composition. The best yield was found for $\mathrm{PbO}: \mathrm{En}$ near 1:2. This complex is colourless and insoluble in water. $\mathrm{PbEnAc}_{2}$ dissolves in DMF and DMSO on heating.

Infrared spectra were recorded on a UR-10 spectrophotometer in the 4000-400 $\mathrm{cm}^{-1}$ region using conventional techniques. Absorptions characteristic of acetate ion were found at $v_{\mathrm{as}}(\mathrm{CO})=1560 \mathrm{~cm}^{-1}$ and at $\nu_{\mathrm{s}}(\mathrm{CO})=1400 \mathrm{~cm}^{-1}$. The difference between the absorptions ( $160 \mathrm{~cm}^{-1}$ ), according to ref. 4 , indicate bridging acetate groups.

Crystallographic measurements were made at $20^{\circ} \mathrm{C}$ using an Enraf Nonius CAD-4 diffractometer operating in the $\omega / 2 \theta$-scan mode (the ratio of scanning rates, $\omega / \theta$, was 1.2). The intensities of 2236 unique reflections were collected within the range $2 \leq \theta \leq 56^{\circ}$ using graphite-monochromated MoKa radiation ( $\lambda=0.71073 \AA$ ). The structure was solved with direct methods and refined by full-matrix leastsquares techniques in the anisotropic approximation. In the refinement 1638 reflections with $I \leq 36$ ( $I$ ) were used. About $60 \%$ of hydrogen atoms were located in difference Fourier maps; positions of the remaining hydrogen atoms were calculated. All hydrogen atoms were included in the final refinement with fixed positional and thermal ( Biso $=6 \AA^{2}$ ) parameters. Convergence was obained at $R=0.027$ and $R_{\epsilon}=0.039$; GOF was 1.46 ( 118 refined parameters; largest peak in the final difference map was $\left.0.90 \mathrm{e} / \AA^{3}\right)$; the weighting scheme $\omega=\left\{\Delta^{2}(F)+0.0016\right.$ $\left.F^{2}\right\}^{-1}$ was used. Corrections for Lorentz and polarization effects as well as an empirical correction for absorption using the DIFABS program ${ }^{5}$ were applied. All structural calculations were carried out with a PDP-11/23 + computer using SDP-PLUS software. ${ }^{6}$ Positional and thermal parameters $\left(B_{e q}\right)$ derived from the last cycle of least square refinement, along with their associated standard deviations are presented in Table 1.

Crystal data for compound of composition $\mathrm{C}_{6} \mathrm{H}_{14} \mathrm{~N}_{2} \mathrm{O}_{4} \mathrm{~Pb}$ are as follows: monoclinic, space group $P 2_{1} / c$, cell parameters $a=5.532(1), b=24.185(5), c=$ $7.630(1) \AA, V=1010.22(47) \AA^{3}, Z=4$; calculated density is $2.534 \mathrm{~g} / \mathrm{cm}^{3} ; \mu=$ $168.1 \mathrm{~cm}^{-1}, F(000)=712$.

## DISCUSSION

The close lead atom coordination environment shown in Figure 1 is formed by two ethylenediamine nitrogen atoms, $\mathrm{N}(1)$ and $\mathrm{N}(2)$, and two oxygen atoms of each acetate group, $0(1)$ and $0(2)$; approximate bonds distances are 2.4-2.6 $\AA$ (Table 2). The remote environment is formed by two other acetate oxygen atoms, $0(2)$ and $0(4 \mathrm{~b})$, which are located at a distance from the lead atom of $2.9-3.0 \AA$. We have observed such a distinction in bonds lengths for lead complexes earlier ${ }^{7,8}$ and one can explain this effect by means of different electron participation in bond formation.

The lead atom is deviates only a little $(0.18 \AA)$ from the plane formed by $O(2)$, $O(3)$ and $O(4 b)$ towards the coordinated ethylenediamine molecule. The lone electron pair is evidently located on the other side of this plane ${ }^{9}$. Therefore, the donor atoms of nearest coordination environment form a bisphenoid, which, taking into account the further environment and the lone electron pair, is transformed into a capped octahedron. ${ }^{9}$

There are two different chelated acetate groups in the complex, cyclic and bridging. Both lead - oxygen interatomic distances for the bridging group are 0.1 $-0.2 \AA$ longer then for the cyclic group. We have previously observed such bridging bond enlargement for ethylenediamine ${ }^{2}$.

Figure 1 Fragment of the $\mathrm{PbEnAc}_{2}$ polymeric chain. The presupposed H -bonds arc shown as dotted lines. Symmetry codes: a) $1+x, y, z$; b) $-1+x, y, z$; c) $x, 0.5+y,-0.5+z$; d) $x, 0.5+y, 0.5+z$.

| $\mathrm{C}(1)-\mathrm{C}(2)$ | 1.51(2) | $\mathrm{O}(2)-\mathrm{C}(1)-\mathrm{C}(2)$ | 120.6(6) |
| (3) | Bridging acetate group |  |  |
| $\mathrm{O}(3)-\mathrm{C}(3)$ | 1.265(9) | $\mathrm{O}(3)-\mathrm{C}(3)-\mathrm{O}(4)$ | 125.1(7) |
| $\mathrm{O}(4)-\mathrm{C}(3)$ | 1.23 (1) | $\mathrm{O}(3)-\mathrm{C}(3)-\mathrm{C}(4)$ | 117.6 (7) |
| $\mathrm{C}(3)-\mathrm{C}(4)$ | 1.51(1) | $\mathrm{O}(4)-\mathrm{C}(3)-\mathrm{C}(4)$ | $117.2(6)$ |
| (4) | En molecule |  |  |
| $\mathrm{N}(1)-\mathrm{C}(5)$ | 1.459(9) | $\mathrm{N}(1)-\mathrm{C}(5)-\mathrm{C}(6)$ | 110.3(7) |
| $\mathrm{N}(2)$-C(6) | 1.48 (2) | $\mathrm{N}(2)-\mathrm{C}(6)-\mathrm{C}(5)$ | 110.8(6) |
| C(5)-C(6) | 1.49(1) |  |  |

The cyclic acetate group is coordinated to the lead atom through $0(1)$ and $O(2)$ atoms and forms a four-membered ring where the angle $\mathrm{O}(1)-\mathrm{C}(1)-\mathrm{O}(2)$ is $c a 122^{\circ}$ and the angle $\mathrm{O}(1)-\mathrm{Pb}-\mathrm{O}(2)$ is $\mathrm{ca} 48^{\circ}$. A difference in $\mathrm{Pb}-\mathrm{O}(1)$ and $\mathrm{Pb}-\mathrm{O}(2)$ bond $(\approx$ $0.4 \AA$ ) distances testifies to the acetate group having a pseudochelate function. ${ }^{10}$ All atoms of this group are located in a plane. The lead atom deviates from this plane by $0.25 \AA$. The dihedral angle between planes formed by $\mathrm{O}(2), \mathrm{O}(3), \mathrm{O}(4 \mathrm{~b})$ and Pb , $\mathrm{O}(1), \mathrm{O}(2)$ atoms is $46.3^{\circ}$.

The second acetate group is a bridging one and links neighboring lead atoms into polymeric chains. The bridging group is distorted slightly more than the cyclic one (the angle $\mathrm{O}(3)-\mathrm{C}(3)-\mathrm{O}(4)$ is $c a 125^{\circ}$ and $\mathrm{C}(3)$ atom is deflected $0.01 \AA$ from the plane formed by other atoms of this group).

The cyclic En molecule forms a five-membered ring where the angle $\mathrm{N}(1)-\mathrm{Pb}-\mathrm{N}(2)$ is $73.0^{\circ}$. The $\mathrm{Pb}-\mathrm{N}-\mathrm{C}$ angles are close to tetrahedral, as is characteristic for this ethylenediamine coordination manner. The N-C distances are $1.47 \AA$, and C-C $1.49 \AA$. The En molecule possesses the gauche conformation with a dihedral angle of $56^{\circ}$.

In the structure, there are two presupposed H -bonds: $\mathrm{N}(1) \ldots \mathrm{O}(1 \mathrm{a})(1+x, y, z)$ and
$\mathrm{N}(1) \ldots \mathrm{O}(2 \mathrm{c})(x, 0.5+y,-0.5+z)$. The first has a length of $2.897 \AA$ and links the noted atoms of one polymeric chain. The second is weaker ( $2.996 \AA$ ) and links different polymeric chains.
