#### Abstract

The reaction of anhydrous copper nitrate with 1-hydroxy-methyl-3,5-dimethyl pyrazole in the presence of 3,5 -dimethyl pyrazole in methanol gave a deep green colored solution, which upon addition of excess sodium perchlorate afforded dark green crystals of bis[3,5-dimethylpyrazole(1methoxy, 3,5-dimethyl pyrazole) $\mathrm{Cu}(\mathrm{II})$ perchlorate] (1) upon slow evaporation of the solvent. The structural assignment of (1) was made in part by elemental analysis and electronic spectroscopy and was confirmed by single crystal X-ray diffraction studies. The crystal structure reveals that compound (1) crystallizes in the monoclinic space group $P 2_{1} / n$ with four molecules in the unit cell of dimensions $a=8.927(3), b=19.019(9)$, and $c=9.794(3) \AA$, and $\beta=112.65(3)^{\circ}$. The structure has been refined to an $R(F)$ factor of 0.029 based on 2110 observed reflections. The geometry around each $\mathrm{Cu}(\mathrm{II})$ center is best described as a square pyramid, with the basal plane occupied by two ligating nitrogen atoms with an average $\mathrm{Cu}-\mathrm{N}$ distance of 1.961 (3) $\AA$ and two bridging alkoxide oxygen atoms with Cu -O distances of $1.915(2)$ and $1.928(2) \AA$, respectively. The axial position is occupied by an oxygen atom from the perchlorate ion with a $\mathrm{Cu}-\mathrm{O}$ distance of 2.390 (2) $\AA$. The Cu atom lies near the basal plane of a pyramid. The two $\mathrm{Cu}(\mathrm{II})$ ions are bridged by two alkoxide groups with a $\mathrm{Cu}-\mathrm{Cu}$ separation of $3.022(1) \AA$, and a $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ bond angle of $103.70(1) .{ }^{\circ}$ Ferromagnetic interaction is found to be operating in this complex, with a room temperature magnetic moment of 2.82 B.M. The electronic absorption spectrum shows a ligand field band at $695 \mathrm{~nm}\left(\varepsilon=98 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ which is expected for $\mathrm{Cu}(\mathrm{II})$ with tetragonal geometry. There is also an additional peak at $350 \mathrm{~nm}\left(\varepsilon=2700 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ which is associated with the charge transfer band from the bridging alkoxide oxygen to $\mathrm{Cu}(\mathrm{II})$.

KEYWORDS: dicopper(II), pyrazole, alkoxo bridge, tetragonal pyramid

## INTRODUCTION

The synthesis and characterization of dinuclear $\mathrm{Cu}(\mathrm{II})$ complexes with one or more bridging ligands continues to be an area of intense research activity. ${ }^{1-3}$ Most of the

[^0]studies center on the magnetic exchange interaction between coupled copper centers, and chemical modelling of the active site of hemocyanin, a binuclear $\mathrm{Cu}(\mathrm{II})$ oxygen transport protein in many species of anthropods and mollusks. ${ }^{2}$ Interestingly, structural and magnetic relationships (especially involving bis ( $\mu$-hydroxo), bis ( $\mu$-alkoxo) and bis ( $\mu$-chloro) bridged compounds) have shown strong correlations. ${ }^{1}$ Both ferromagnetic and anti-ferromagnetic exchange interactions have been observed with the magnitude dependent on the identity of the bridging ligand, the $\mathrm{Cu}-\mathrm{Cu}$ separation, the bridging angles, the metal-bridge ligand bond length and metal ion stereochemistry. The use of chelating ligands incorporating pyrazole groups has drawn strong interest. ${ }^{4-7}$ For example, in $[\mathrm{CuL}]_{2}(\mathrm{OH})_{2}$ where L is the tris(pyrazolyl)borate(-1), a strong anti-ferromagnetic coupling was reported and its peroxo-bridged analogue showed a close spectroscopic match to the active sites in oxyhemocyanin. ${ }^{4-7}$ We are particularly interested in 1-hydroxymethyl-3,5dimethylpyrazole. ${ }^{8}$ This planar heteroatomic ligand should allow more control over structural factors that determine magnetic and electronic exchange properties in dinuclear complexes. We present here the synthesis, spectroscopic and structural characterization of a di-alkoxo bridged dicopper complex.

## EXPERIMENTAL

1-hydroxyl methyl-3,5-dimethyl-pyrazole
This ligand was synthesized following a reported procedure. ${ }^{8}$

## $\left[\mathrm{Cu}\left(3,5 \text {-dimethylpyrazole)(1methoxy-3,5-dimethyl-pyrazole) }\left(\mathrm{ClO}_{4}\right)\right]_{2}\right.$

To a solution of $0.25 \mathrm{~g}(2.00 \mathrm{mmol})$ of 1-hydroxylmethyl-3,5-dimethyl-pyrazole in 30 mL of methanol was added $0.38 \mathrm{~g}(2.00 \mathrm{mmol})$ anhydrous $\mathrm{Cu}(\mathrm{II})$ nitrate, followed by addition of $0.19 \mathrm{~g}(2.0 \mathrm{mmol})$ of 3,5 -dimethyl-pyrazole. The resultant solution was refluxed for 3 h , and cooled to room temperature. Sodium perchlorate $(0.5 \mathrm{~g}$, 4 mmol ) was added, and stirring continued for an additional thirty min. The solution was filtered and the filtrate was allowed to evaporate slowly to give dark green crsytals $0.5 \mathrm{~g}(0.65 \mathrm{mmol}) 65 \%$ yield. Anal Calc. for $\mathrm{CuC}_{11} \mathrm{H}_{17} \mathrm{~N}_{4} \mathrm{ClO}_{5}(\%)$ : C, $34.37 \mathrm{H}, 4.42 \mathrm{~N}, 14.58$ Found: C, $34.90 \mathrm{H}, 4.63 \mathrm{~N}, 14.81$. Visible spectra 350 nm $\left(\varepsilon=2700 \mathrm{~cm}^{-1} \mathrm{M}^{-1}\right)$, (LMCT) and $695 \mathrm{~nm}\left(\varepsilon=98 \mathrm{~cm}^{-1} \mathrm{M}^{-1}\right) \mathrm{d}$-d band. Physical Measurements: C, H, and N analyses were performed by Schwarzkopf Microanalytical Laboratory, NY, U.S.A. The UV/Visible spectrum was measured with a Perkin Elmer Lamda II spectrophotometer in the range of $240-800 \mathrm{~nm}$. The solution paramagnetic susceptibility of 1 was measured by the shift in the proton resonance of $t$-butyl group of the $t$-butanol in methanol using a Varian EM360A NMR spectrometer.

## $X$-ray Structure Determination

A dark green rod $(0.10 \times 0.15 \times 0.50 \mathrm{~mm})$ of (1) was placed in oil at the end of a glass fiber and transported to a Nonius CAD-4 diffractometer with graphite-
monochromatized Mo $\mathrm{K} \alpha(0.71073 \AA$ ) radiation. The pertinent crystallographic data are summarised in Table 1. The final unit cell parameters were obtained by least square fit of 25 accurately centered reflections measured in the ranges $17.5^{\circ}<2 \varnothing<19.9^{\circ}$ and the intensity data were collected at 293(2) K in the range of $2^{\circ}<2 \varnothing<25^{\circ}$. Three standard reflections monitored every $3600 s$ did not show any significant change in intensity during the data collection. An absorption correction (SHELX-76 ${ }^{99}$ ) was applied with the minimum and maximum transmission factors of 0.731 and 0.852 respectively. The 4161 total reflections were merged to 2699 independent data (Rint $=0.018$ ), and 2110 with $\mathrm{I}>2 \sigma(\mathrm{I})$ were used in the structure refinement. The structure solution and refinement were carried out by the direct method (SHELXS-86) ${ }^{9 \mathrm{~b}}$ and leastsquare procedure (SHELXL-93) ${ }^{9 \mathrm{c}}$ [with only one restraint: the $\mathrm{N}-\mathrm{H}$ bond was restrained to $0.9(1) \AA$ ]. The final cycles of refinement converged at $R(F)=0.029$, $w R\left(F^{2}\right)=0.061$ based on 2110 observed reflections with [I>2.0 $\left.\sigma(\mathrm{I})\right]$. Anisotropic displacement parameters were applied for all non-hydrogen atoms. For the non-H atoms, the coordinates and equivalent isotropic displacement parameters are given in Table 2. The H atoms were refined with isotropic displacement parameters.

## RESULTS AND DISCUSSION

## Spectroscopy

Spectral data for this dicopper complex are consistent with a square pyramidal geometry about each of the $\mathrm{Cu}(\mathrm{II})$ centers and may be taken as evidence that no geometrical change occurs going from the solid state to solution (vide infra). Electronic spectra of (1) show a broad peak at $\lambda=695 \mathrm{~nm}\left(\varepsilon=98 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ which is in agreement with a tetragonally-based coordination geometry. ${ }^{10}$ In addition, a very strong peak centered at $\lambda=350 \mathrm{~nm}\left(\varepsilon=2700 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ is present and is assigned to the charge transfer mediated absorption from the bridging methoxide to $\mathrm{Cu}(\mathrm{II})$. Similar uv/visible peak positions have been observed in other alkoxo dicopper complexes. ${ }^{11}$

## Description of the Structure

The dimeric $\left[\mathrm{Cu}(3-5 \text { dimethylpyrazole })\left(\mu_{2}-1-\mathrm{OCH}_{2} \text {-3,5-dimethylpyrazole }\right)\left(\mathrm{ClO}_{4}\right)\right]_{2}$ unit and atomic numbering scheme is shown in Figure 1. The structure consists of a dicopper complex with two bridging methoxide groups. The five-coordinate environment about each copper atom is best described as tetragonal pyramidal. Occupying the apex of the pyramid is one of the oxygen atoms of the perchlorate, and the four basal positions are comprised of one nitrogen atom from the 3,5-dimethyl pyrazole and a nitrogen and two bridging methoxide oxygen atoms from the 1 -methoxy-3,5-dimethylpyrazole ligand. The latter yields a five-membered chelate ring, with the Cu atom. The halves of the dinuclear unit are related by

Figure 1 The molecular structure and labelling scheme of $\left[\mathrm{Cu}(3,5\right.$-dimethylpyrazole $)\left(\mu_{2}-1-\mathrm{OCH}_{2}-\right.$ 3,5-dimethylpyrazole) $\left.\left(\mathrm{ClO}_{4}\right)\right]_{2}$, with thermal ellipsoids drawn at the $50 \%$ probability level.
crystallographic inversion symmetry, the dimeric plane composed of $\mathrm{Cu}, \mathrm{Cu}^{\prime}$, $\mathrm{O}(5), \mathrm{O}(5)^{\prime}, \mathrm{N}(2), \mathrm{N}(3), \mathrm{N}(2)^{\prime}$ and $\mathrm{N}(3)^{\prime}$ is also essentially planar. The geometry in this compound is not unusual as it is also observed in [ $\mathrm{Cu}(\mathrm{DMAEP}) \mathrm{OH}]_{2}\left[\mathrm{ClO}_{4}\right]_{2}, 12 \mathrm{a}$ where DMAEP $=2$-(2-dimethylaminoethyl)pyridine, $[\mathrm{Cu}(\mathrm{EAEP}) \mathrm{OH}]_{2}\left[\mathrm{ClO} \mathrm{C}_{4}\right]_{2}{ }^{12 b}$ where EAEP is 2-(2-ethylaminoethyl)pyridine and both nitrate ${ }^{12 \mathrm{c}}$ and sulphate ${ }^{12 \mathrm{~d}}$ salts of $[\mathrm{Cu}(\text { bipy }) \mathrm{OH}]_{2}{ }^{2+}$. The bond distances and angles presented in Table 3 are consistent with those in similar complexes. ${ }^{12 \mathrm{a}-\mathrm{d}}$ The $\mathrm{Cu}-\mathrm{Cu}$ ' separation being $3.022(1) \AA$ and the $\mathrm{Cu}-\mathrm{O}(5)$ and $\mathrm{Cu}-\mathrm{O}(5)^{\prime}$ bond lengths being $1.915(2)$, and $1.931(2) \AA$. The bond angles of $\mathrm{Cu}-\mathrm{O}(5)-\mathrm{Cu}$ ' and $\mathrm{O}(5)-\mathrm{Cu}-\mathrm{O}(1)$ ' of $103.6(1)$ and $76.43(9)^{\circ}$, respectively, are in range with those found in previously investigated di- $\mu$-alkoxo copper(II) complexes. ${ }^{12 a, b, c, d, 13-18}$ The bond length between the copper center and the perchlorate oxygen atom $\mathrm{Cu}-\mathrm{O}(4)$ of $2.390(2) \AA$ is considerably shorter than at in $\left[\mathrm{Cu}(\mathrm{DMAEP}) \mathrm{OH}_{2}{ }_{2}{ }^{12 \mathrm{a}}\right.$ where $\mathrm{Cu}-\mathrm{O}(2)$ is $2.721(4) \AA$. The geometry of the perchlorate group is essentially tetrahedral with $\mathrm{Cl}-\mathrm{O}$ bond lengths ranging from $1.426(3)$ to $1.449(2) \AA$ and the $\mathrm{O}-\mathrm{Cl}-\mathrm{O}$ bond angles of $108.3(1)$ to $109.8(2)^{\circ}$. The dihedral angle between the mean planes of the 3,5 -dimethylpyrazole and the 1 -methoxy-3,5 dimethylpyrazole in the coordination sphere is $70(1)^{\circ}$. There is extensive inter- and intra-molecular hydrogen bonding involving the pyrazole NH and the oxygen atoms of the perchlorate and the alkoxide. The shortest interatomic contact distance involves $\mathrm{O}(5)$ of $1-\mathrm{OCH}_{2}-3,5$ dimethyl pyrazole and $\mathrm{H}(4) \mathrm{N}$ of the adjacent pyrazole at $2.48 \AA$ (see Figure 2). The inter- and intra-molecular distances less than or equal to the sum of the associated van der Waals radii are

Symmetry transformations used to generate equivalent atoms: ${ }^{a}-x,-y,-z$.
$\mathrm{O}(1)-\mathrm{O}(5)=3.11 \AA, \mathrm{O}(4)-\mathrm{O}(5)(-\mathrm{x},-\mathrm{y},-\mathrm{z})=3.05 \AA, \mathrm{O}(4)-\mathrm{N}(3)=3.05 \AA$, $\mathrm{O}(4)-\mathrm{N}(4)=2.94 \AA$, and $\mathrm{O}(2)-\mathrm{N}(4)(1-\mathrm{x},-\mathrm{y},-\mathrm{z})=2.96 \AA$. The extensive interand intra-molecular hydrogen bonding contributes to the overall stability of this complex in the solid state. The effective magnetic moment of $\mathbf{1}$ in solution at 295 K is $2.82 \mu_{\mathrm{B}}{ }^{19}$ This observed value at 295 K is comparable to the magnetic moment value of $2.64 \mu_{\mathrm{B}}$ at 200 K reported for ferromagnetically coupled binuclear $\left[\mathrm{Cu}_{2}(\mathrm{O})\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{O}_{2} \mathrm{CMe}\right)(\mathrm{bpy})_{2}\right]\left(\mathrm{ClO}_{4}\right)_{2}{ }^{18}$ in which the two Cu centers are square pyramid and the $\mathrm{Cu}-\mathrm{Cu}$ bond length is $3.035(2) \AA$ and the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle was $103.8(2)^{\circ}$. Although dinuclear $\mathrm{Cu}(\mathrm{II})$ complexes usually display antiferromagnetic exchange interactions, ferromagnetic systems are by no means rare. ${ }^{14-18}$ Complex 1 is a new member of this latter group. The exchange interactions within

Figure 2 Hydrogen bonding (thin lines) in the crystal structure of $\left[\mathrm{Cu}(3,5\right.$-dimethylpyrazole) $)\left(\mu_{2}-1-\right.$ $\mathrm{OCH}_{2}-3,5$-dimethylpyrazole) $\left.\left(\mathrm{ClO}_{4}\right)\right]_{2}$ 1, which connects the dimer along the crystallographic $a$-axis ("needle" axis of the crystal).
$\operatorname{bis}\left(\mu\right.$-hydroxo) $\mathrm{Cu}(\mathrm{II})$ systems have been well investigated, ${ }^{18}$ and the magnitude and sign of the interaction have been found to be sensitive to a number of factors including the $\mathrm{Cu}-\mathrm{O}-\mathrm{Cu}$ angle. The bridging angle of $103.6(1)^{\circ}$, a relatively small value may be contributing to the observed magnetism.

## Supplementary material

Tables of H atom coordinates (Table S-1), anisotropic displacement parameters (Table S-11), the torsion angles (Table S-111) and observed and calculated structure factor amplitudes (Table S-IV) are available from the authors on request.
