#### Abstract

Mono- and binuclear palladium complexes were isolated from reactions of $\left[\mathrm{PdCl}_{4}\right]^{2-}$ with heterocyclic nitrogen donor ligands depending on the type of ligand. Bidentate ligands $\mathrm{L}-\mathrm{L}$, where $\mathrm{L}-\mathrm{L}=2$-( $2^{\prime}$-pyridyl)-benzimidazole (PBI), 2-pyrazinecarboxylic acid (PC) and 2-pyrazinecarboxamide (PCA) gave the monosubstituted $\left[\mathrm{Pd}(\mathrm{L}-\mathrm{L}) \mathrm{Cl}_{2}\right]$ complex. Binuclear palladium complexes $\left[\mathrm{Pd}(\mathrm{L}) \mathrm{Cl}_{2}\right]_{2}$ were obtained from reactions with the monodentate ligands 2-aminothiazole (AT) or 2-aminobenzimidazole (ABI). Elemental analyses and spectroscopic studies of the reported complexes allowed structures to be proposed. The thermal properties of the complexes were also investigated by thermogravimetric techniques.

Keywords: Palladium; Nitrogen ligands; Complexes; Spectra; Thermal analysis

## INTRODUCTION

Interest in transition metal complexes of heterocyclic compounds containing nitrogen as a donor atom such as pyridines, bi- and polypyridines, azines and their derivatives has been stimulated by their electrochemical properties, magnetic coupling interactions, and catalytic and photocatalytic processes [1-5]. In the last decade, complexes of azines, especially those of pyrazines, such as 2,3 -bis( $2^{\prime}$-pyridyl)pyrazine, 2,3 -bis( $2^{\prime}$-pyridyl)quinoxaline and 2-pyrazinecarboxamide and their derivatives, have found applications in the fields of photochemistry and catalysis [6-9]. On the other hand, the chemistry of $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$, and their applications in catalysis, is versatile [10,11]. Many azine derivatives have a vital role in biology. Some azines act as anticancer or antiallergic reagents [12,13]. Coordination compounds of $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ have found application

as antitumor reagents [14]. Cisplatin analogs of some benzimidazole derivatives as well as their equivalent palladium compounds have been characterized by X-ray structure analysis. The antitumor activities of the corresponding platinum compounds were compared to the activity of cisplatin in one fibroblast and eight brain tumor cell lines [15]. Also, complexes of the type $[\mathrm{M}(\mathrm{bpy})(\mathrm{L}-\mathrm{L})] \mathrm{NO}_{3}\left[\mathrm{M}=\mathrm{Pd}(\mathrm{II})\right.$ or $\mathrm{Pt}(\mathrm{II})$, bpy $=2,2^{\prime}$-bipyridine, $\mathrm{L}-\mathrm{L}=$ anion of 2-pyridinecarboxylic acid or 2-pyrazinecarboxylic acid] have been found to bind calf thymus DNA, possibly through hydrogen bonding [16].

Mono- and binuclear $\mathrm{Pd}(\mathrm{II})$ and $\mathrm{Pt}(\mathrm{II})$ complexes are known. For example, the [ M (dithiocarbamato) $(\mathrm{L})] \mathrm{Cl}$ complexes $(\mathrm{M}=\mathrm{Pd}$ or $\mathrm{Pt}, \mathrm{L}=$ methioninol $)$ have been prepared by reacting methioninol with the appropriate $[\mathrm{M} \text { (dithiocarbamato) } \mathrm{Cl}]_{n}$ complex in a $1: 1$ molar ratio. At a 1:2 molar ratio, the binuclear species $\left[\mathrm{M}_{2}\right.$ (dithiocarbamato) ${ }_{2}$ $(\mathrm{L}) \mathrm{Cl}_{2}$ ] were obtained [17]. Mononuclear complexes with the general formula $\mathrm{M}(\mathrm{L})_{2}$ $\mathrm{Cl}_{2}(\mathrm{M}=\mathrm{Pd}$ or $\mathrm{Pt}, \mathrm{L}=$ functionalized nitrogen-containing tertiary phosphine ligands namely $o$-, $m$ - and $p$-dimethylphosphinyl-methylene-oxyaniline) have been reported [18]. Vibrational studies, physical and analytical data indicated that the ligands in the complexes coordinated through the amino group to form square-planar platinum and palladium complexes.

Our interest in the coordination chemistry of heterocyclic ligands containing nitrogen atoms such as pyrazines and imidazoles [19-22] has prompted us to investigate the reactions of $\mathrm{Pd}(\mathrm{II})$ with some selected heterocyclic ligands (Scheme 1).

purchased from Aldrich. $\left[\mathrm{PdCl}_{4}\right]^{2-}$ solutions were prepared by heating a solution of $0.083 \mathrm{~g} \mathrm{PdCl} 2(0.50 \mathrm{mmol})$ in $50 \mathrm{~cm}^{3} \mathrm{H}_{2} \mathrm{O}$ and $0.5 \mathrm{~cm}^{3} \mathrm{HCl}(37 \%)$ at $70^{\circ} \mathrm{C}$. The clear solution of $\left[\mathrm{PdCl}_{4}\right]^{2-}$ was filtered and left to cool.

## Instruments

IR measurements ( KBr pellets) were carried out on a Shimadzu 8000 FT-IR spectrophotometer. NMR measurements were performed on a Varian-Mercury 300 MHz spectrometer. Samples were dissolved in $\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}$ with TMS as internal reference. Thermogravimetric analyses (TG and DTG) were carried out under $\mathrm{N}_{2}$ atmosphere with a heating rate of $10^{\circ} \mathrm{C} / \mathrm{min}$. using a Shimadzu DT-50 thermal analyzer. The complexes were also characterized by elemental analysis (Perkin-Elmer 2400 CHN instrument) and mass spectroscopy (Finnigan MAT SSQ 7000). Table I gives the elemental analysis, color, yield and mass spectrometric data for the complexes.

## Syntheses of Complexes

A ligand solution ( 0.5 mmol dissolved in minimum ethanol) was added dropwise with constant stirring to a $\left[\mathrm{PdCl}_{4}\right]^{2-}$ solution $(0.5 \mathrm{mmol})$. Immediate precipitation of the complexes occurred. (Complexes of AT and ABI ligands required heating $\left(60^{\circ} \mathrm{C}\right)$ to precipitate). The solid was filtered off, washed by ethanol and then recrystallized from hot ethanol. The complexes were dried on a vacuum line.

## RESULTS AND DISCUSSION

Depending on the ligand, mono- or binuclear palladium complexes were isolated from the reactions of $\left[\mathrm{PdCl}_{4}\right]^{2-}$ solution with heterocyclic nitrogen donor ligands in ethanol [Eqs. (1) and (2), Scheme 1].

${ }^{a}{ }_{\mathrm{s}}$, strong; m, medium; w, weak. ${ }^{\mathrm{b}} \mathrm{s}$, singlet; d, doublet; m, multiplet. ${ }^{\mathrm{c}} \delta(\mathrm{py})=620-540 \mathrm{~cm}^{-1} .{ }^{\mathrm{d}} \delta(\mathrm{py})=687-579 \mathrm{~cm}^{-1}$. ${ }^{e} v(\mathrm{OH})=3425 \mathrm{~cm}^{-1}, \nu(\mathrm{C}=\mathrm{O})=1720 \mathrm{~cm}^{-1} .{ }^{\mathrm{f}} v(\mathrm{C}=\mathrm{O})=1713 \mathrm{~cm}^{-1}$.

Interaction of bidentate ligands $\mathrm{L}-\mathrm{L}[\mathrm{L}-\mathrm{L}=2$-(2'-pyridyl)-benzimidazole (PBI), 2-pyrazinecarboxylic acid (PC) and 2-pyrazinecarboxamide (PCA)] with $\left[\mathrm{PdCl}_{4}\right]^{2-}$ resulted in immediate precipitation of the monosubstituted derivative $\left[\mathrm{Pd}(\mathrm{L}-\mathrm{L}) \mathrm{Cl}_{2}\right]$. Elemental analysis and mass spectral data confirmed the proposed formula (Table I). The PBI derivative was crystallized with three water molecules, the PC derivative isolated with five $\mathrm{H}_{2} \mathrm{O}$, while the PCA species separated with two $\mathrm{H}_{2} \mathrm{O}$ molecules. The number of waters of crystallization was determined from the TG analysis (vide infra). The IR spectra of the complexes showed the characteristic bands of the ligands due to functional groups such as $\mathrm{NH}, \mathrm{C}=\mathrm{N}, \mathrm{C}=\mathrm{O}$ and $\mathrm{C}=\mathrm{C}$ with the appropriate shifts (Table II). The ${ }^{1} \mathrm{H}$ NMR spectra of the complexes also displayed signals due to the different proton nuclei in ligands (Table II). The existence of the band due to the NH group in the IR spectrum of the $\left[\mathrm{Pd}(\mathrm{PBI}) \mathrm{Cl}_{2}\right]$ complex, which was also confirmed by NMR, indicated that coordination of ligand occurred without proton displacement. For the $\left[\mathrm{Pd}(\mathrm{PC}) \mathrm{Cl}_{2}\right]$ complex, no NMR signal was observed for the OH of the carboxylic moiety. However, this signal was not observed in the spectrum of the ligand itself. Reactions of $\mathrm{M}(\mathrm{CO})_{6}(\mathrm{M}=\mathrm{Mo}$ and W$)$ with PBI resulted in the formation of $\left[\mathrm{M}(\mathrm{CO})_{4}(\mathrm{PBI})\right]$ complexes [23]. Also, reactions of $\left[\mathrm{M}_{3}(\mathrm{CO})_{12}\right](\mathrm{M}=\mathrm{Ru}$ and Os$)$ with PBI gave $\left[\mathrm{Ru}(\mathrm{CO})_{3}(\mathrm{PBI})\right]$ and $\left[\mathrm{Os}(\mathrm{CO})_{2}(\mathrm{PBI})_{2}\right][21]$. Spectroscopic studies of these complexes showed that the ligand occupied equatorial positions without proton displacement. Interaction of $\left[\mathrm{M}_{3}(\mathrm{CO})_{12}\right](\mathrm{M}=\mathrm{Ru}$ and Os$)$ with either PCA or PC gave the tricarbonyl derivatives $\left[\mathrm{M}(\mathrm{CO})_{3}(\mathrm{~L}-\mathrm{L})\right]$. The two ligands are bidentate and occupied equatorial sites [24]. Scheme 2 gives the proposed structures of the palladium complexes

2

3

SCHEME 2 The palladium complexes of the bidentate ligands.
(1-3). The structure of $\mathbf{1}$ was previously determined by crystal structure analysis, which showed that the PBI ligand is bidentate and the two chlorines are cis.

In order to gain more insight into the structure and thermal stability of the palladium complexes, thermal studies on the solid complexes using thermogravimetric (TG) and differential thermogravimetric (DTG) techniques were performed. The TG and DTG plots of the mononuclear complexes exhibited well-defined and non-overlapping decomposition steps. The TG plot of the $\left[\mathrm{Pd}(\mathrm{PBI}) \mathrm{Cl}_{2}\right]$ complex showed that it decomposed in a single step. This occurred in the $690-790 \mathrm{~K}$ temperature range with a net weight loss of $58.2 \%$. The percentage weight loss was consistent with the elimination of three $\mathrm{H}_{2} \mathrm{O}$ molecules and the PBI group. A metal-containing residue of $\mathrm{PdCl}_{2}$ was left $(41.8 \%)$. Investigation of the $\left[\mathrm{Pd}(\mathrm{PC}) \mathrm{Cl}_{2}\right]$ complex showed that the TG and DTG plots exhibited two well-defined and non-overlapping decomposition steps. The first decomposition step occurred in the $505-585 \mathrm{~K}$ range with a net weight loss of $23.2 \%$, which corresponds to the elimination of five $\mathrm{H}_{2} \mathrm{O}$ molecules. The percentage weight loss in the second stage ( $31.5 \%$ ) occurred in the $585-705 \mathrm{~K}$ range and is consistent with the elimination of the pyrazinecarboxamide molecule. The TG plot of the $\left[\mathrm{Pd}(\mathrm{PCA}) \mathrm{Cl}_{2}\right]$ complex showed a similar decomposition pattern to that of the $\left[\mathrm{Pd}(\mathrm{PC}) \mathrm{Cl}_{2}\right]$ complex with two decomposition steps in the temperature range $496-718 \mathrm{~K}$ with a total net weight loss of $47.6 \%$. The first decomposition step occurred at $496-572 \mathrm{~K}$ (weight loss $10.6 \%$ ) corresponding to elimination of two $\mathrm{H}_{2} \mathrm{O}$ molecules. The second step, a loss of $37.0 \%$, was consistent with elimination of the PCA ligand leaving a metalcontaining residue, $\mathrm{PdCl}_{2}$.

The binuclear palladium complexes $\left[\mathrm{Pd}(\mathrm{L}) \mathrm{Cl}_{2}\right]_{2}[\mathrm{~L}=2$-aminothiazole (AT) or 2-aminobenzimidazole (ABI)] were obtained from reactions of ethanolic solutions of $\left[\mathrm{PdCl}_{4}\right]^{2-}$ with L at elevated temperature. The mass spectral data of the two complexes, Table I, indicated dimers. Both complexes crystallized with a water molecule $/ \mathrm{mol}$ of compound as determined from TG analysis. The IR and ${ }^{1} \mathrm{H}$ NMR spectra of the two complexes displayed the appropriate shifts due to complex formation (Table II).

4

5

SCHEME 3 The palladium complexes of the monodentate ligands.

As expected from the structure of the two ligands, the $v(\mathrm{C}=\mathrm{N})$ band in the IR spectrum of $\left[\mathrm{Pd}(\mathrm{AT}) \mathrm{Cl}_{2}\right]_{2}$ complex was shifted to lower frequency while it was shifted to higher frequency in the case of $\left[\mathrm{Pd}(\mathrm{ABI}) \mathrm{Cl}_{2}\right]_{2}$. For example, the IR spectra of the $1: 1$ molecular adducts derived from 2-aminobenzimidazole as a donor and either trinitrobenzene or picric acid as an acceptor showed that the $\nu(\mathrm{C}=\mathrm{N})$ bands were shifted to higher frequency [25]. On the other hand, similar charge-transfer complexes with 2-aminothiazole exhibited shifts to lower frequencies [26]. The proposed structures of the two palladium complexes $(\mathbf{4}, \mathbf{5})$ are given in Scheme 3.

Thermal studies of the two binuclear palladium complexes provided further insight into the proposed structures as well as their thermal stability. The TG plot of the $\left[\mathrm{Pd}(\mathrm{AT}) \mathrm{Cl}_{2}\right]_{2}$ complex showed three decomposition steps in the temperature range $442-763 \mathrm{~K}$. The first two steps were overlapping with unresolved peaks. These two peaks occurred at $442-582 \mathrm{~K}$ with a net weight loss of $19.9 \%$, due to elimination of a water molecule and an AT ligand. The third decomposition step ( $660-762 \mathrm{~K}, 17.3 \%$ ) could be due to elimination of the second AT ligand. Thermal decomposition of the $\left[\mathrm{Pd}(\mathrm{ABI}) \mathrm{Cl}_{2}\right]_{2}$ complex exhibited a similar pattern to that observed for $\left[\mathrm{Pd}(\mathrm{AT}) \mathrm{Cl}_{2}\right]_{2}$. However, a different thermal decomposition mechanism occurred. Two decomposition peaks are observed in the temperature range $430-792 \mathrm{~K}$ with a net weight loss of $44.2 \%$. The first decomposition peak ( $430-492 \mathrm{~K}, 8.1 \%$ ) could be due to elimination of a water molecule and two $\mathrm{NH}_{3}$ groups. The second decomposition peak, which occurred at $500-792 \mathrm{~K}$ with a net weight loss of $36.1 \%$, corresponded to material decomposition to leave a $\mathrm{PdCl}_{2}$ residue ( $55.8 \%$ ).
