Metal chalcogenide semiconductors such as sulfides ( $\text{Ag}_2\text{S}$ ,  $\text{CdS}$ ,  $\text{ZnS}$ ), selenides ( $\text{CuGaSe}_2$ ,  $\text{CuInSe}_2$ ,  $\text{ZnSe}$ ) and tellurides ( $\text{Ag}_2\text{Te}$ ,  $\text{CdTe}$ ,  $\text{ZnTe}$ ) have been studied because of their optoelectronic applications [1, 2]. In particular, silver sulfide ( $\alpha\text{-Ag}_2\text{S}$ , acanthite) is a *n*-type semiconductor [3, 4] which has been commonly used in photoconductors, photovoltaic and solar cells as well as in infra-red detectors.

Our studies on the reactivity, in air, in the solid state between  $\text{Ag}_2\text{S}$  and  $\text{Ag}_2\text{SO}_4$  showed that both reagents were not mutually inert and reacted to give two phases:  $\beta\text{-Ag}_6\text{S}_3\text{O}_4$  and  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$  [5–7]. We found that these phases showed polymorphism [8]. Low-temperature polymorphic forms of  $\text{Ag}_6\text{S}_3\text{O}_4$  and  $\text{Ag}_8\text{S}_4\text{O}_4$  compounds ( $\alpha$ -phases) can be obtained, as precipitates, only in the reaction occurring between aqueous solutions of  $\text{AgNO}_3$  and  $\text{Na}_2\text{S}_2\text{O}_3$  [8, 9]. High-temperature polymorphic modification of  $\text{Ag}_6\text{S}_3\text{O}_4$  is formed by heating  $\text{Ag}_2\text{S}/\text{Ag}_2\text{SO}_4$  mixture according to the following reaction [5, 7]:

High-temperature polymorphic form of  $\text{Ag}_8\text{S}_4\text{O}_4$ ,  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$ , can be obtained by heating an initial mixture comprising 75.00 mol% of  $\text{Ag}_2\text{S}$  and 25.00 mol% of  $\text{Ag}_2\text{SO}_4$  according to Equation 2 [6, 7]:

$\alpha\text{-Ag}_6\text{S}_3\text{O}_4$  undergoes irreversible, endothermic polymorphic transition to  $\beta$ -phase at 221 °C [9].  $\beta\text{-Ag}_6\text{S}_3\text{O}_4$  melts at 390 °C [10]. Low-temperature polymorphic form of  $\text{Ag}_8\text{S}_4\text{O}_4$  undergoes irreversible, endothermic polymorphic transition to  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$  at 223 °C [9]. The latter phase melts at 400 °C [6].  $\alpha$ -,  $\beta\text{-Ag}_6\text{S}_3\text{O}_4$  and  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$  crystallize in the monoclinic system while  $\alpha\text{-Ag}_8\text{S}_4\text{O}_4$  is tetragonal [5, 6, 8, 9]. Thermopower measurements at room temperature showed that  $\alpha$ -modifications are *p*-type semiconductors while  $\beta$ -modifications are of *n*-type [11].

$\alpha$ - and  $\beta$ -forms of  $\text{Ag}_6\text{S}_3\text{O}_4$  and  $\text{Ag}_8\text{S}_4\text{O}_4$  compounds were prepared as described previously [5, 6, 9]. X-ray photoelectron spectroscopy (XPS) measurements were performed using an ESCA 100 VSW (Manchester, UK) spectrometer with a Mg  $K_{\alpha}$  X-ray

Figure 1 XPS spectrum of S2p for  $\alpha\text{-Ag}_8\text{S}_4\text{O}_4$ .Figure 2 XPS spectrum of S2p for  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$ .

source ( $h\nu = 1253.6$  eV). The residual pressure inside the analysis chamber was in the  $2 \times 10^{-8}$  mbar range. X-ray photoelectron spectra were calibrated using the  $\text{Ag}3d_{5/2}$  signal from an Ag-foil (BE = 368.2 eV). The samples were sputtered with an Ar ion beam before the spectra were recorded (energy of  $\text{Ar}^+$  ions—2.5 keV, time of sputtering—10 min.).

Figs 1 and 2 show the spectra of  $\text{S}2p_{3/2-1/2}$  for  $\alpha$ - and  $\beta\text{-Ag}_8\text{S}_4\text{O}_4$ , respectively. The BE values of  $\text{S}2p$  for  $\text{Ag}_2\text{S}$ , a mixture of  $\text{Ag}_2\text{S}/\text{Ag}_2\text{SO}_4$ , both polymorphic forms of  $\text{Ag}_6\text{S}_3\text{O}_4$  and  $\text{Ag}_8\text{S}_4\text{O}_4$  and for some reference sulfur compounds are listed in Table I. As summarized in the 4th column of Table I, the BE values of the  $\text{S}2p_{3/2}$  peaks, recorded for  $\text{Ag}_2\text{S}$  and  $\text{Ag}_2\text{S}/\text{Ag}_2\text{SO}_4$  mixture ( $\text{S}(-\text{II})$ ): 161.20 eV, 161.50 eV and  $\text{S}(+\text{VI})$ : 168.30 eV,

remain in good agreement with the literature values [12, 15]. Results of XPS studies, performed for low- and high-temperature polymorphic forms of Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub> and Ag<sub>8</sub>S<sub>4</sub>O<sub>4</sub>, show a presence of only two different types of sulfur atoms. One of them (S2p<sub>3/2</sub> BE: 161.50 ÷ 161.80 eV) could be attributed to S(–II) sulfur. The other one (S2p<sub>3/2</sub> BE: 167.80 ÷ 168.00 eV) could be assigned to S(+VI) sulfur in SO<sub>3</sub>S tetrahedron analogous to S(+VI) sulfur in Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> [13, 14]. From a comparison of the measured S2p<sub>3/2</sub> BE values for Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub> and Ag<sub>8</sub>S<sub>4</sub>O<sub>4</sub> compounds with the published values [12–15] it follows that neither S(+VI) in SO<sub>4</sub><sup>2–</sup> nor S(+IV) in SO<sub>3</sub><sup>2–</sup> as well as nor S(–I) in S<sub>2</sub><sup>2–</sup> sulfur atoms can be seen in the analyzed phases.

The Ag3d<sub>5/2–3/2</sub> spectra for  $\alpha$ - and  $\beta$ -Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub> are showed in Figs 3 and 4, respectively. In Table II, the BE values of Ag3d electron doublet, measured for Ag<sub>2</sub>S,

Ag<sub>2</sub>S/Ag<sub>2</sub>SO<sub>4</sub> mixture,  $\alpha$ - and  $\beta$ -forms of Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub> and Ag<sub>8</sub>S<sub>4</sub>O<sub>4</sub>, are given together with analogous, published values for some silver(I) compounds [16–19]. The BE values of Ag3d<sub>5/2–3/2</sub> for AgO (Ag<sup>I</sup>Ag<sup>III</sup>O<sub>2</sub>—two kinds of silver atoms [20]) are given in Table II, too. In this work, the BEs of the Ag3d<sub>5/2</sub> peak were recorded at 367.70 eV and at 367.90 eV for Ag<sub>2</sub>S and Ag<sub>2</sub>S/Ag<sub>2</sub>SO<sub>4</sub> mixture, respectively. These values are very similar to those reported by other authors (Table II) [12, 16–19] and they are assigned to Ag(+I) silver atoms. XPS investigations show that the BE values of Ag3d<sub>5/2</sub> for both forms of Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub> and Ag<sub>8</sub>S<sub>4</sub>O<sub>4</sub> were shifted, in comparison to analogous BE value for AgO, to higher BE values. Likewise, the BEs of Ag3d<sub>5/2</sub> measured for analyzed phases are in very good agreement with those observed in Ag<sub>2</sub>S, Ag<sub>2</sub>S/Ag<sub>2</sub>SO<sub>4</sub> mixture and Ag<sub>2</sub>O [16–19]. These facts

Figure 3 XPS spectrum of Ag3d for  $\alpha$ -Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub>.

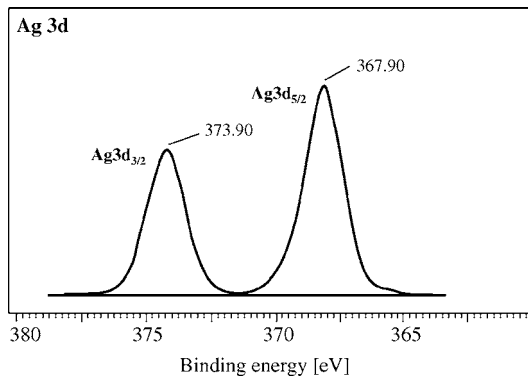

Figure 4 XPS spectrum of Ag3d for  $\beta$ -Ag<sub>6</sub>S<sub>3</sub>O<sub>4</sub>.

point to the presence of Ag(+I) silver in analyzed compounds.

### Acknowledgment

The authors thank Ms. Z. Piwowska (Jagiellonian University, Faculty of Chemistry, Kraków, Poland) for carrying out the XPS measurements.
