From the reaction of p-trifluoromethylbenzanilide (55 g, 0.207 mole), dimethylaniline (87.5 g, 0.72 mole), and POCl₃ (41.5 g, 0.27 mole) 45 g of a solid product was obtained. It was recrystallized from boiling EtOH and sublimed at reduced pressure. Purification was accomplished by treatment with excess NaHCO₃ solution giving a yellow solid, mp 149–152°, positive DNPH test. Recrystallization from boiling EtOH raised the melting point to 153–154° and the compound was chromatographically pure (tlc) and had the correct elemental analysis.

Procedure C. Benzophenone Guanylhydrazone Hydrochloride (1).—Benzophenone (18.2 g, 0.066 mole) and aminoguanidine hydrochloride (13 g, 0.118 mole) in 100 ml of glacial AcOH were refluxed for 64 hr and then cooled. A solid separated, was filtered, washed with cold EtOH, and dried. A white powder was obtained and recrystallized from EtOH, weight 26 g (94.6%), mp 292–295° dec. Recrystallization from H₂O–EtOH (4:1) gave a white crystalline solid which still showed a trace of impurity in tlc, mp 292–294° dec, and had the correct elemental analysis. When H₂O–EtOH was used as a reaction solvent only a 50% yield of the crude product was obtained.

p-Chlorobenzophenone Guanylhydrazone Hydrochloride (6).—p-Chlorobenzophenone (12.5 g, 0.058 mole) and aminoguanidine hydrochloride (7.0 g, 0.063 mole) in 100 ml of H₂O–EtOH (1:1) and a few drops of concentrated HCl were refluxed for 2 days, after which half of the solvent was removed under reduced pressure. A solid separated, was filtered, washed with a large amount of H₂O then with hot PhH, and dried. The crude material weighed 12.3 g (68.5%), mp 268–271°. The recrystallized product from H₂O–EtOH (5:1) had mp 280–282° dec, showed a trace of impurity in tlc, and had the correct elemental analysis.

Procedure D. 4,4′-Ditrifluoromethylbenzophenone Guanylhydrazone Hydrochloride (4).—4,4′-Ditrifluoromethylbenzophenone (6.2 g, 0.02 mole) and aminoguanidine hydrochloride (6.2 g, 0.056 mole) in 15 ml of ethylene glycol and 6 drops of concentrated HCl were refluxed for 0.5 hr. The cooled solution was added to 150 ml of H₂O. A solid separated, was filtered, washed (H₂O, PhH, Et₂O), and dried, 4.9 g. This material was recrystallized (H₂O) yielding 1.9 g (23.8%) of white powder, mp 306–308° dec, chromatographically pure (tlc).

4-Bromo-3′,5′-ditrifluoromethylbenzophenone Guanylhydrazone Hydrochloride (22).—4-Bromo-3′,5′-ditrifluoromethylbenzophenone (5.0 g, 0.013 mole) and aminoguanidine hydrochloride (5.0 g, 0.045 mole) in 12 ml of DMAC and 6 drops of concentrated HCl were refluxed for 0.5 hr. The reaction mixture was cooled to room temperature and 100 ml of H₂O was added. A viscous white material separated and was left in the open air for 5 days, after which it solidified, weighing 5.5 g, mp 65–118°, positive AgNO₃ test. The crude product was recrystallized from 25 ml of boiling toluene. A crop was obtained which still had a broad melting point range. The material was stirred and boiled for 0.5 hr with 40 ml of PhH and filtered, yielding 1.3 g, mp 190–196°, positive AgNO₃ test. The solid was stirred and boiled with 200 ml of CHCl₃–C₆H₅CH₃ and filtered, yielding 0.8 g (15%) of product, chromatographically pure (tlc).

4-Bromo-4′-trifluoromethylbenzophenone guanylhydrazone p-toluenesulfonate (21) was prepared according to procedure D. Aminoguanidine p-toluenesulfonate was prepared by adding p-toluenesulfonic acid (385 g, 2.24 moles) with stirring to 2 l. of H₂O and heating the stirred mixture to approximately 80°. Aminoguanidine bicarbonate (272 g, 2 moles) was added to it and the stirred mixture was brought to boiling, whereupon the solid dissolved. The solution was filtered hot and allowed to cool. Crystals formed, were washed with a large amount of H₂O then with EtOH, and dried, yielding 277 g (68.5%) of a crystalline solid, mp 201–203°. Recrystallization (hot H₂O, EtOH–H₂O (4:1)) raised the melting point to 205–206°, tlc (C₆H₆–EtOH (95:5), 25 min) showing a trace of impurity. Anal. (C₈H₁₄N₄O₃S) C, H, N, S.

N-Dialkylaminoalkylbiphenylamines as Antimalarial and Antischistosomal Agents[1]

WARREN G. DUNCAN AND DAVID W. HENRY

Department of Pharmaceutical Chemistry, Stanford Research Institute, Menlo Park, California 94025

A series of N-dialkylaminoalkylbiphenylamines and N′-substituted N-biphenylpiperazines have been prepared and evaluated as antimalarial and antischistosomal agents. Potentially general procedures were developed for constructing four- and six-carbon aminoalkyl chains on the biphenylamine nuclei, utilizing succinic anhydride and 6-bromohexanoic acid, respectively. No important effects against experimental *Plasmodium berghei* or *Schistosoma mansoni* infections in mice were observed, but several of the compounds displayed significant *in vitro* activity against a series of nonparasitic microorganisms.

We have prepared the series of biphenylamine derivatives listed in Tables I and II as part of a program to develop novel antimalarial and antischistosomal agents. In general, the compounds of Table I are derived from the mirasan[2] series of antischistosomal drugs (e.g., **1**) by three types of modification: replacement of chlorine by phenyl, insertion of a p-chlorophenyl group into the open *meta* position of the toluidine ring, and extension of the basic side chain. The compounds of Table II are based on a group of antischistosomal N-(3-chloro-p-

tolyl)piperazines[2,3] that developed from the mirasan group. The possibility that incorporation of a phenyl fraction into these systems would produce interesting antiparasitic activity was suggested by the marked increase in the antimalarial activity of synthetic quinine analogs when phenyl substituents were inserted into the 2 position.[4] Indeed, one such compound (**2**) has been

shown to be effective against both malaria[4] and schistosomiasis[5] in experimental animal systems.

1

2
Chemistry.—The synthesis of the new compounds resolved itself into two areas: preparation of asymmetric biphenylamines and subsequent attachment of an appropriate side chain to the amine group. Four biphenylamines were employed. One of these, 2-

biphenylamine, was commercially available. The synthesis of a second, 6-methyl-3-biphenylamine (**3**), was reported recently.[6] A third, **4**, was obtained by
3. X = Z = H; Y = CH₃
4. X = Y = H; Z = Cl
5. X = Z = Cl; Y = CH₃

6. R = H
7. R = CH₂C₆H₅

(6) D. W. Henry, *J. Heterocyclic Chem.*, **3**, 503 (1966).

catalytic reduction of the known precursor, 4-chloro-3-nitrobiphenyl.[7] The preparative procedure for the fourth biphenylamine, **5**, is outlined in Scheme I. The

SCHEME I

starting material, 3,5-dinitro-*p*-toluic acid (**8**), was converted to methyl 3-chloro-5-iodo-*p*-toluate (**9**) by a series of reductions and Sandmeyer reactions. Mixed Ullmann coupling of the latter with *p*-chloroiodobenzene provided intermediate biphenyl ester **10** in 25% yield. Ester **10** was converted to the corresponding amide and rearranged to biphenylamine **5** by the Hofmann reaction.

Linear side chains, two, four, and six carbons in length and bearing terminal tertiary aliphatic amino functions, were attached to the amine functions of the biphenylamines to form the compounds of Table I. The two-carbon side chains were readily incorporated in one step by means of commercially available 2-chloro-triethylamine. Convenient and potentially general methods for assembling the four- and six-carbon chains were developed and are outlined in Scheme II. Suc-

prepared from biphenylamine **3** by means of a general method that has been reported separately.[6] N-Mono-substituted piperazine **6** was obtained from N'-benzyl precursor **7** by catalytic hydrogenolysis. Compound **6** was converted to maleamide **29** with maleic anhydride and to phenoxypropyl compound **30** by a standard acylation–reduction sequence.

Tables I and II present characterization data on the N-dialkylaminoalkylbiphenylamines and N-biphenylyl-piperazines prepared in this study. Almost all of the final products were oils and were characterized and bio-assayed as their oxalate salts. The structures of all final products and most intermediates were confirmed by proton magnetic resonance spectroscopy.

Biological Activity.—The compounds were assayed against lethal, blood-induced *Plasmodium berghei* infections in mice[8] as part of the Walter Reed Army Institute of Research malaria program. Tables I and II list the increases in survival time and the toxicities displayed by the compounds prepared in this study. Two compounds, **21** and **30**, appeared to prolong survival times up to 3.5 days at 640 mg/kg and to show a dose–response relationship in initial tests, but this activity could not be confirmed when the tests were repeated. Compound **21** appeared especially variable in its effect, and the two series of results presented in Table I represent the two limiting assays. The majority of compounds were without appreciable beneficial effect and were toxic at the highest doses.[9] Quinine and chloroquine are included for comparison.

Compounds **18**, **20**, **22**, **24–26**, **28**, and **7** were tested for antischistosomal activity in mice infected with lethal inocula of *Schistosoma mansoni* cercariae.[10] All were ineffective at nontoxic doses.

When tested *in vitro*, a number of these compounds were appreciably inhibitory to bacteria, yeast, or a fungus. All compounds of Tables I and II were ex-

SCHEME II
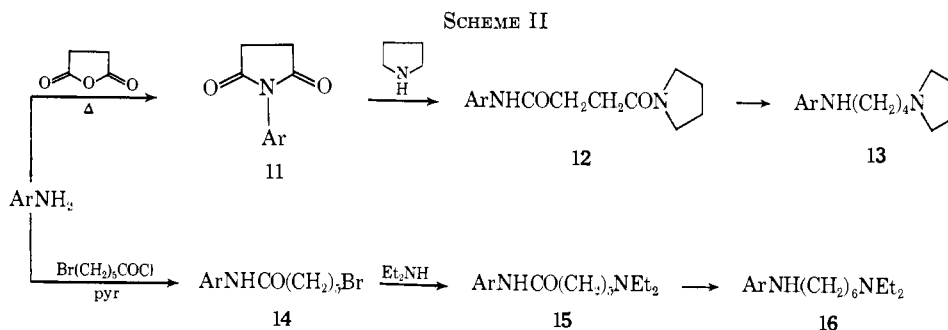

cinic anhydride, when heated with the biphenylamines, gave N-substituted succinimides (**11**), which opened to succinamides (**12**) upon refluxing with pyrrolidine. Reduction of these with borane–THF or LiAlH₄ provided the four-carbon side chain derivatives (**13**).

The six-carbon side chain series was obtained from 6-bromohexanoic acid *via* the acid chloride. Reaction with the biphenylamines gave 6-bromohexanamides (**14**), which were refluxed with excess diethylamine to give 6-diethylaminohexanamides (**15**). These provided the six-carbon diamines (**16**) upon reduction.

Piperazine derivatives **7** and **28** (Table II) were

amined except **17**, **18**, and **6**. Data on those showing significant activity are summarized in Table III; the test employed has been previously described.[11]

(7) C. E. Kaslow and R. M. Summers, *J. Org. Chem.*, **20**, 1738 (1944).

(8) Performed by Dr. Leo Rane at the University of Miami, Miami, Fla; see T. S. Osdene, P. B. Russell, and L. Rane, *J. Med. Chem.*, **10**, 431 (1967).

(9) The possibility that the toxicity of these compounds was due to their use as oxalate salts cannot be excluded. If this were the case, the effect was not consistent since two oxalate salts (**7** and **25**) were not toxic. The toxicity of **6** (Table II) as the dihydrochloride suggests that the series possesses at least some intrinsic toxicity.

(10) We are grateful to Colonel William E. Rothe of the Walter Reed Army Institute of Research for communicating these results and providing a description of the test procedure. Lieutenant Colonel Myron G. Radke directed the schistosomiasis assay work.

Experimental Section[12]

4'-Chloro-3-biphenylamine (4).—A suspension of 20.0 g (0.086 mole) of 4-chloro-3'-nitrobiphenyl[13] in 300 ml of EtOH was hydrogenated in the presence of 0.4 g of PtO₂ in a low-pressure Parr apparatus for 0.5 hr. The product, 14.3 g (82%, mp 69–70°), was purified by passage through basic Al₂O₃ (CHCl₃ elution) and crystallization from petroleum ether (bp 30–60°). Blakey and Scarborough[13] report a melting point of 82° for this compound.

5-Iodo-3-nitro-*p*-toluic Acid.—The diazonium salt solution, formed by treatment at 0–5° of 196.2 g (1.00 mole) of crude 3-amino-5-nitro-*p*-toluic acid[14] in 1600 ml of 6 N HCl with 75.9 g (1.10 moles) of NaNO₂ in 150 ml of H₂O, was poured slowly into a stirred solution of 199.2 g (1.2 moles) of KI in 1500 ml of H₂O. N₂ was evolved immediately and the very crude product (246.5 g) precipitated. After partial purification by sublimation at 200° (0.2 mm), the product was used directly in the next step; yield 104.5 g (34%), mp 190–210°. Recrystallization (MeOH–H₂O) gave a pure sample, mp 213–215°. *Anal.* (C₈H₆INO₄) C, H.

Methyl 3-Iodo-5-nitro-*p*-toluate.—A solution of the acid (30.7 g, 0.10 mole) and 60 ml of concentrated H₂SO₄ in 350 ml of MeOH was refluxed for 0.5 hr and chilled in ice. The crystalline product (27.5 g, 86%, mp 99–102°) was collected, washed with H₂O, and dried at 60° *in vacuo*. Recrystallized (MeOH–H₂O), it melted at 100–101.5°. *Anal.* (C₉H₈INO₄) C, H.

Methyl 3-Amino-5-iodo-*p*-toluate.—Catalytic reduction (27 hr) of methyl 3-iodo-5-nitro-*p*-toluate (32.1 g, 0.10 mole) with Raney Ni in warm MeOH (400 ml) in a low-pressure Parr apparatus provided this product. The filtered reaction mixture was chilled to give 26.1 g (90%, mp 131–134°). Recrystallized (MeOH–H₂O), it melted at 135–136.5°. *Anal.* (C₉H₁₀INO₂) C, H.

Methyl 3-Chloro-5-iodo-*p*-toluate (9).—A well-stirred suspension of methyl 3-amino-5-iodo-*p*-toluate hydrochloride salt, prepared by diluting a solution of 62.8 g (0.216 mole) of the amine in 300 ml of DMF with 110 ml of 6 N HCl, was treated slowly at 0° with a solution of 16.4 g (0.238 mole) of NaNO₂ in 40 ml of H₂O. The diazonium salt solution was added slowly, with stirring, to a Cu₂Cl₂ solution prepared from 62.6 g of CuSO₄·5H₂O by Fieser's procedure.[15] The crude product, which precipitated immediately with N₂ evolution, was purified by chromatography over Al₂O₃, using 5% Et₂O in 30–60° petroleum ether as eluent; yield 56.1 g, mp 68–75°. Recrystallization (MeOH–H₂O) gave material of mp 73–74°. Preparative glpc gave an analytical specimen (mp 75.5–76.5°). *Anal.* (C₉H₈ClIO₂) C, H.

Methyl 4',5-Dichloro-6-methylbiphenyl-3-carboxylate (10).—Methyl 3-chloro-5-iodo-*p*-toluate (28.0 g, 0.09 mole), 4-chloroiodobenzene (47.0 g, 0.2 mole), and 100 g of Cu powder were

heated together at 230° for 4 hr. The reaction mixture was cooled and the crude product was extracted from the inorganic material with hot C₆H₆. The extract was evaporated *in vacuo* to leave a partially crystalline residue. Extraction of the residue with boiling pentane left a solid that melted at 125–135°. The pentane extract was chromatographed over 800 g of silica gel, using pentane as the initial eluent. When elution of by-product 4,4'-dichlorobiphenyl ceased, 5% Et₂O in pentane was used to remove the product (8.2 g, 25%). Recrystallized from heptane, it melted at 71.5–73°. *Anal.* (C₁₅H₁₂Cl₂O₂) C, H, Cl.

The insoluble residue remaining from the pentane extraction consisted largely of 4,4'-dichlorobiphenyl, but a second component, dimethyl 5,5'-dichloro-6,6'-dimethyl-3,3'-biphenyldicarboxylate, could be isolated by silica gel chromatography. Pentane eluted the 4,4'-dichlorophenyl and Et₂O, the new product. Crystallization from CCl₄–pentane gave colorless crystals melting at 176–176.5°. *Anal.* (C₁₈H₁₆Cl₂O₄) C, H, Cl.

4',5-Dichloro-6-methyl-3-biphenylcarboxylic Acid.—Hydrolysis of the methyl ester (10) in 3 N NaOH in 50% aqueous EtOH (reflux, 2 hr) provided this acid after acidification of the reaction mixture: mp 204–206° (MeOH–H₂O). *Anal.* (C₁₄H₁₀Cl₂O₂) C, H, Cl.

4',5-Dichloro-6-methyl-3-biphenylcarboxamide.—Treatment of the acid with SOCl₂ gave the acid chloride; this was treated with excess gaseous NH₃ in C₆H₆ solution to provide the amide, mp 180–180.7° (MeOH–H₂O), yield 82%. *Anal.* (C₁₄H₁₁Cl₂NO) C, H.

4',5-Dichloro-6-methyl-3-biphenylamine (5).—To a solution of 6.72 g (24 mmoles) of 4',5-dichloro-6-methyl-3-biphenylcarboxamide in 100 ml of MeOH was added consecutively, with stirring, a solution of 56 mmoles of NaOMe in 40 ml of MeOH and 3.84 g (24 mmoles) of Br₂. The mixture was refluxed for 15 min and cooled. AcOH was added (to pH 6) and the solvent was removed *in vacuo*. The solid residue was washed with H₂O and dried to give 7.17 g of crude methyl N-(4',5-dichloro-6-methyl-3-biphenylyl)carbamate, mp 140–147°. The product contained some unreacted starting amide. The carbamate was hydrolyzed by refluxing for 1 hr in 100 ml of 3 N NaOH in 50% aqueous EtOH. The EtOH was removed *in vacuo* and the residue was extracted with Et₂O. The combined Et₂O extracts were dried over Na₂SO₄ and evaporated to dryness *in vacuo*. The residue was extracted with hot heptane to remove the product. The insoluble residue consisted of 1.9 g of crude sodium 4',5-dichloro-6-methyl-3-biphenylcarboxylate. The heptane extracts gave 4.61 g (80%) of product, mp 81–82°, upon cooling in Dry Ice. *Anal.* (C₁₃H₁₁Cl₂N) C, H, N.

N-(2-Diethylaminoethyl)biphenylamines. General Procedure for 17, 20, 22, and 25.—The biphenylamines were refluxed overnight in 95% EtOH with 2 molar equiv of 2-chlorotriethylamine hydrochloride. The pH of the reaction mixture was adjusted to 8 with dilute NaOH. Excess Na₂S₂O₃ was added (to destroy excess alkylating agent) and refluxing was continued for 0.5 hr. The reaction mixture was cooled, diluted with H₂O, and extracted with Et₂O to isolate the crude products. For 17, 20, and 22, chromatography over silica gel (Et₂O elution) provided the pure oily products. Vacuum distillation (bp 128–144°, 0.15 mm) was used to purify 25. Oxalate salts were formed in high yield by mixing molar equivalents of the free bases and oxalic acid in Me₂CO solution. Recrystallization from Me₂CO served to purify the salts when necessary (17 and 20). Yields ranged from 32 to 58%.

A modification of this procedure, using equimolar amounts of biphenylamine and 2-chlorotriethylamine free base in aqueous DMF, gave similar results.

N-Biphenylylsuccinimides (11). General Procedure.—Equimolar amounts of the biphenylamine and succinic anhydride were heated together at 200–215° for 2 hr. Recrystallization of the dark melts, once or twice, provided products suitable for the next reaction with the exception of 33, for which column chromatography over Al₂O₃ (Et₂O–petroleum ether elution) was necessary. Table IV summarizes pertinent data for these compounds.

N-Biphenylyl-N',N'-tetramethylenesuccinamides (12). General Procedure.—Solutions (ca. 20%) of the N-biphenylylsuccinimides (11) in pyrrolidine were refluxed for 1–2 hr. After cooling, the solutions were treated with excess 3 N or 6 N HCl and the solid precipitated products were isolated by decantation or filtration. Compound 38 precipitated as an oil and was isolated by extraction with CHCl₃. It subsequently crystallized from CCl₄ to give material melting at ca. 70° when examined immedi-

(12) Melting points were taken in capillary tubes on a Mel-Temp apparatus and are corrected. Infrared and proton magnetic resonance spectra were obtained on Perkin-Elmer Model 137 and Varian HR100 or A60 instruments, respectively. Microanalyses were performed by the Stanford Research Institute Analytical Department. Where analyses are indicated only by symbols of the elements, analytical results were within ±0.4% of the theoretical values.

TABLE IV

N-BIPHENYLYLSUCCINIMIDES (11)

No.	Biphenylamine used in prepn	Yield, %	Mp, °C	Crystn solvent	Formula[a]
31	3	62	125.5–127	MeOH	$C_{17}H_{15}NO_2$
32	4	36	165–166	MeOH	$C_{16}H_{12}ClNO_2$
33	5	38	114–115	CCl₄–pentane	$C_{17}H_{13}Cl_2NO_2$
34	2-Biphenylamine	80	132–133.5	Aq MeOH	$C_{16}H_{13}NO_2$

[a] All compounds were analyzed for C, H.

ately. The melting point rose spontaneously over several days to a maximum of 97.5–99°. This behavior was apparently due to a crystalline transition because low-melting material gave the same combustion analysis as older, high-melting samples. Characterization data for these compounds are given in Table V.

TABLE V

N-BIPHENYLYL-N',N'-TETRAMETHYLENESUCCINAMIDES (12)

No.	Biphenylamine used in prepn	Yield, %	Mp, °C	Crystn solvent	Formula[a]
35	3	89	150–152	Aq MeOH	$C_{21}H_{24}N_2O_2$
36	4	92	160–162	Aq MeOH	$C_{20}H_{21}ClN_2O_2$
37	5	95	210–211	MeOH	$C_{21}H_{22}Cl_2N_2O_2$
38	2-Biphenylamine	70	97.5–99	CCl₄	$C_{20}H_{22}N_2O_2$

[a] All compounds were analyzed for C, H.

N-[4-(1-Pyrrolidino)butyl]biphenylamines. General Procedures for 18, 21, 23, and 26.—Solutions of the N-biphenylylsuccinamides in THF were added at 0° to four- to sevenfold molar equivalents of LiAlH₄ or BH₃ in THF[16] over a few minutes. After several hours of refluxing, the reaction mixtures were cooled and, in the case of LiAlH₄ reduction, H₂O was slowly and carefully added with stirring until the gray color of the salts changed to white. The filtrate, after removal of the inorganic salts, yielded crude products requiring chromatography over silica gel (Et₂O, Et₂O–MeOH elution) for purification.

The cooled BH₃ reaction mixtures were treated with 6 N HCl, the THF was boiled off, and refluxing was continued for 1 hr to hydrolyze the unusually stable amine–BH₃ complexes present. Neutralization with NaOH and Et₂O extraction provided essentially pure products as the free bases. Yields with both reducing agents were in the 70–80% range. Oxalic acid salts were formed in Me₂CO solutions.

N-(6-Bromohexanoyl)biphenylamines (14). General Procedure.—A solution of the biphenylamine in pyridine was treated over 5 min with a 10% molar excess of 6-bromohexanoyl chloride (from the acid and SOCl₂), with stirring at 0°. After stirring a few minutes at room temperature, a small piece of ice was added to hydrolyze excess acid chloride. The mixture was diluted with excess 3 N HCl and the crude product was isolated by Et₂O extraction. Back-extraction of the product solution with dilute NaHCO₃ removed 6-bromohexanoic acid. The product from amine 3, N-(6-bromohexanoyl)-6-methyl-3-biphenylamine, melted at 85–87° (57%, MeOH–H₂O). Anal. (C₁₉H₂₂BrNO) C, H. The amide from amine 5, N-(6-bromohexanoyl)-4',5-dichloro-6-methyl-3-biphenylamine, melted at 120–122.5° (MeOH). Anal. (C₁₉H₂₀BrCl₂NO) C, H. The amide from 2-biphenylamine was oily and was not characterized.

N-(6-Diethylaminohexyl)biphenylamines. General Procedure for Compounds 19, 24, and 27.—A 5–10% solution of the N-(6-bromohexanoyl)biphenylamine in Et₂NH was refluxed for ca. 4 hr and most of the solvent was removed in vacuo. The residue was partitioned between H₂O and Et₂O. The ether-soluble N-(6-diethylaminohexanoyl)biphenylamines (15) were reduced to N-(6-diethylaminohexyl)biphenylamines and purified in essentially the same manner as the corresponding four-carbon chain analogs. Crystalline dioxalate salts formed upon mixing 1 molar equiv of amine with 2 molar equiv of oxalic acid in Me₂CO solution. Monooxalate salts failed to form.

1-(6-Methyl-3-biphenylyl)piperazine Dihydrochloride (6).—A solution of 6.6 g (19 mmoles) of 1-benzyl-4-(6-methyl-3-biphenylyl)piperazine (7) in 260 ml of absolute EtOH, after addition of 13.4 ml of 3 N HCl (40 mmoles), was hydrogenated at atmo-

spheric pressure in the presence of 1.32 g of 10% Pd–C. H₂ uptake stopped at 95% of theoretical after 1 hr. The mixture was warmed to dissolve some crystalline precipitate of product and the filtered solution was concentrated to ~150 ml by boiling. After cooling, the crystalline product was collected, washed with Et₂O, and dried; yield 3.8 g (62%), mp 225–255° dec. A sample prepared in a similar previous experiment, mp 210–265° dec, was analyzed.

1-(cis-3-Carboxyacryloyl)-4-(6-methyl-3-biphenylyl)piperazine (29).—A solution of 862 mg (3.42 mmoles) of 1-(6-methyl-3-biphenylyl)piperazine in 3 ml of anhydrous THF was treated with 335 mg (3.42 mmoles) of maleic anhydride in 3 ml of THF. After very brief heating (~1 min) on the steam bath, the mixture was cooled and slowly diluted to 20 ml with Et₂O while stirring. The flask was seeded and cooled at −20° overnight to give 891 mg (74%) of product, mp 139.5–141.5°. It was recrystallized from THF for analysis.

1-[3-(p-t-Butylphenoxy)propyl]-4-(6-methyl-3-biphenylyl)piperazine Hydrochloride (30).—A C₆H₆ solution (10 ml) of 1.32 g (5.2 mmoles) of 1-(6-methyl-3-biphenylyl)piperazine (6) was treated with 1.0 ml of Et₃N and then with a C₆H₆ solution (5 ml) of 1.66 g (6.7 mmoles) of 3-(p-t-butylphenoxy)propionyl chloride. After 10 min, the mixture was diluted with 50 ml of Et₂O and was extracted four times with diluted NaOH. The crude 1-[3-(p-t-butylphenoxy)propionyl]-4-(6-methyl-3-biphenylyl)piperazine (2.52 g) was chromatographed over 50 g of Merck basic Al₂O₃ to give 1.89 g of pure product.

The pure propionylpiperazine was reduced with BH₃–THF[16] and worked up as in the reduction of the biphenylylsuccinamides (12). The crude product (HCl salt) was water insoluble; it was isolated by filtration, washed with H₂O, and recrystallized from 25 ml of 95% EtOH to give 1.38 g (67%) of product in two crops (mp 150–153°). Above the melting point, recrystallization occurred, with a final melting point of 220–230° dec. The first crop was analyzed after drying for 0.5 hr at 70° in vacuo.

3-(p-t-Butylphenoxy)propionitrile was prepared from p-t-butylphenol and acrylonitrile in 65% yield by the general method of Lichtenberger, et al.;[17] mp 52–55° (aqueous EtOH). Anal. (C₁₃H₁₇NO) C. H.

3-(p-t-Butylphenoxy)propionic Acid.—Hydrolysis of 10.0 g (49 mmoles) of the acid in a mixture of 25 ml of concentrated HCl and 30 ml of glacial AcOH produced 10.4 g of crude acid (mp 82–91°) after dilution of the reaction mixture with 170 ml of H₂O; mp 91–94° (aqueous MeOH). Anal. (C₁₃H₁₈O₃) C, H.

Schistosomiasis Drug-Testing Procedure.[10]—Groups of five mice 40–60 days of age were exposed by tail immersion to 2000–3000 cercariae of Schistosoma mansoni. A single dose (640, 1280, or 1920 mg/kg, peanut oil suspension) of the test chemical was administered subcutaneously 1–3 days postexposure. Control mice infected with these heavy cercarial inocula die between days 18 and 30, with a mean survival time of 25 days. Since a few control mice (~2%) survive the heavy cercarial exposure, a single survivor or a single mouse still alive after 30 days cannot be considered as evidence of drug activity. Early mortality (days 1–15) is excluded from the analysis of mean survival time. A mean survival time exceeding 30 days suggests antischistosomal activity in this test. Mice surviving to day 49 are sacrificed for total worm count. With niridazole, at 640 mg/kg, mortality in this test is only 20% and surviving mice do not harbor adult schistosomes at necropsy.

(16) H. C. Brown and P. Heim [J. Am. Chem. Soc., 86, 3566 (1964)] reported the use of this reagent for the reduction of amides.
