

for typical examples of the synthetic method (Scheme I).

***N*<sup>α</sup>-Dansyl-L-arginine (12).** To a solution of L-arginine (10.8 g, 62 mmol) and K<sub>2</sub>CO<sub>3</sub> (23.7 g, 172 mmol) in H<sub>2</sub>O (100 mL) was added dansyl chloride (25 g, 92.7 mmol) in Et<sub>2</sub>O (100 mL) with stirring at 0–5 °C. After the solution was stirred for 2 days at room temperature, the precipitate was collected, washed with H<sub>2</sub>O (30 mL) and Et<sub>2</sub>O (30 mL) successively, and then recrystallized from 50% aqueous MeOH to give 12 (20.4 g, 81.0%): mp 199–200 °C.

***N*<sup>α</sup>-Dansyl-L-arginine Methyl Ester Dihydrochloride Monohydrate (10).** A suspension of 12 (1.0 g, 2.5 mmol) in MeOH (15 mL) was cooled to 0–5 °C and SOCl<sub>2</sub> (2.4 g, 25 mmol) was added dropwise with vigorous stirring. After stirring for 2 h at room temperature, the mixture was refluxed for 2 h. After evaporation of the solvent from the mixture, the residue was triturated in cooled H<sub>2</sub>O and Et<sub>2</sub>O. The solid obtained was recrystallized from MeOH–Et<sub>2</sub>O to yield 10 (1.2 g, 92%): mp 147–150 °C.

***N*<sup>α</sup>-Dansyl-L-arginine *n*-Butyl Ester Bis(*p*-toluenesulfonate) (15).** A mixture of 12 (1.0 g, 2.5 mmol), *p*-TsOH·H<sub>2</sub>O (1.0 g, 5.3 mmol), and *n*-BuOH (10 mL) was heated for 30 min at 100 °C. After the addition of benzene (100 mL), the mixture was refluxed for 3 h with removing water by azeotropic distillation. The solvent was evaporated in vacuo and the residue was triturated in petroleum ether–Et<sub>2</sub>O, filtered, and recrystallized from

acetone to give 15 (1.9 g, 95%): mp 160–164 °C.

**Inhibition Studies of Clotting Activity of Thrombin.** To the mixture of 0.8 mL of 0.12% fibrinogen dissolved in borate-saline buffer (pH 7.4) and 0.1 mL of various concentrations of the inhibitor to be tested was added 0.1 mL of 5 units/mL bovine thrombin (Mochida Pharmaceutical). The assay was carried out at 25 °C, and the time from the addition of thrombin to the formation of a clot was recorded.

**Hydrolysis Studies by Thrombin and Trypsin.** The rates of hydrolysis of test compounds were determined titrimetrically at 37 °C and pH 8.0 with a pH-stat fitted with an automatic burette (Toa Electronics). The reaction mixture contained 1 mM test compounds, 0.15 M KCl, and 50 units of thrombin or 1.8 μg of trypsin in a total volume of 7 mL.

**Acknowledgment.** The authors thank M. Sugano and A. Sugiyama for their technical assistance and Dr. S. Hattori, General Manager of Biosciences Laboratory, Central Research Laboratories, Mitsubishi Chemical Industries Limited, for his valuable advice and encouragement throughout the work. We are also indebted to members in Systems Engineering Laboratory, Central Research Laboratories, Mitsubishi Chemical Industries Limited, for elemental analyses.

## Thrombin Inhibitors. 2. Amide Derivatives of *N*<sup>α</sup>-Substituted L-Arginine

A series of *N*<sup>α</sup>-(arylsulfonyl)-L-arginine amide derivatives with substituted or unsubstituted naphthalene and heterocyclic compounds as the *N*<sup>α</sup>-substituent was prepared and tested as inhibitors of the clotting activity of thrombin. *N*-*n*-Butyl and *N*-*n*-butyl-*N*-methyl derivatives of *N*<sup>α</sup>-dansyl-L-arginine amide were the most inhibitory of *N*-alkyl and *N,N*-dialkyl derivatives of *N*<sup>α</sup>-dansyl-L-arginine amide. Their inhibitory effect was as potent as that of *N*<sup>α</sup>-dansyl-L-arginine *n*-butyl ester, with an *I*<sub>50</sub> of 2 × 10<sup>-6</sup> M. *N*<sup>α</sup>-Substituted naphthalenesulfonyl-L-arginine amide derivatives of 4-methyl- and 4-ethylpiperidine also showed a potent inhibition with an *I*<sub>50</sub> of 10<sup>-7</sup> to 10<sup>-6</sup> M. The most potent inhibitor in this study was 1-[*N*<sup>α</sup>-(4,6-dimethoxynaphthalene-2-sulfonyl)-L-arginyl]-4-methylpiperidine, with an *I*<sub>50</sub> of 7.5 × 10<sup>-8</sup> M. Arginine amide derivatives of 4-methyl- or 4-ethylpiperidine with tetralin or an oxygen-containing heterocyclic compound as a *N*<sup>α</sup>-substituent showed an inhibition with an *I*<sub>50</sub> less than 10<sup>-5</sup> M. *N*-Monosubstituted derivatives of *N*<sup>α</sup>-dansyl-L-arginine amide were not hydrolyzed at all by thrombin and were hydrolyzed very slowly by trypsin, and *N,N*-disubstituted derivatives were not hydrolyzed at all by both enzymes.

*N*<sup>α</sup>-Dansyl-L-arginine *n*-propyl or *n*-butyl ester has been shown to inhibit the clotting activity of thrombin but to be hydrolyzed by thrombin and trypsin.<sup>1</sup> Therefore, these compounds are considered to be hydrolyzed easily in vivo and would be inappropriate as an antithrombotic agent. It is, however, noteworthy that compounds with a high affinity to thrombin were found in L-arginine derivatives. We therefore aimed to obtain thrombin-inhibitory L-arginine amide derivatives which have the advantage of protection from hydrolysis. In this paper, we synthesized various *N*<sup>α</sup>-(arylsulfonyl)-L-arginine amide derivatives with substituted or unsubstituted naphthalene and heterocyclic compounds in *N*<sup>α</sup>-substituents and examined the inhibi-

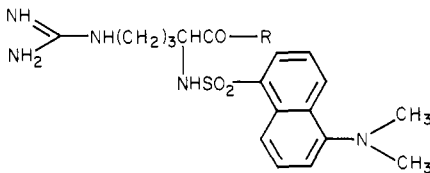

Scheme I

tory effect on thrombin in order to investigate the relationship between a structure and an inhibitory effect on thrombin. A part of this work has been reported briefly<sup>2</sup> and presented orally.<sup>3,4</sup>

<sup>a</sup> These samples, except 11, were synthesized via the general route illustrated in Scheme I. See Experimental Section.

<sup>b</sup> Melting points are uncorrected. <sup>c</sup> All compounds were analyzed for C, H, N, S, and halogen; analytical results were within ±0.4% of the theoretical values. <sup>d</sup> *I*<sub>50</sub> was defined as the concentration at which the clotting time was prolonged by twice the control. <sup>e</sup> Amorphous solid. <sup>f</sup> 2CH<sub>3</sub>COOH salt. This sample was synthesized via the general route illustrated in Scheme II. See Experimental Section.

Scheme II

**Chemistry.** *N*<sup>α</sup>-Dansyl-L-arginine amide derivatives of primary amines listed in Table I, except 11, were synthesized by displacement of the methyl ester portion of the ester *N*<sup>α</sup>-dansyl-L-arginine methyl ester described previously<sup>1</sup> with primary amines, as outlined in Scheme I. Other compounds were synthesized via the general route illustrated in Scheme II. *N*<sup>α</sup>-(*tert*-Butyloxycarbonyl)-*N*<sup>α</sup>-nitro-L-arginine (III) was condensed with the appropriate amine by the mixed anhydride method using isobutyl chloroformate and Et<sub>3</sub>N in dry THF. After the removal of the Boc group of IV by HCl in AcOEt or CF<sub>3</sub>COOH, the amino group of V was sulfonylated with various arylsulfonyl chlorides in the presence of Et<sub>3</sub>N in CHCl<sub>3</sub>. Hydrogenolysis (Pd/H<sub>2</sub>) or acidolysis (HF, anisole) of IV afforded *N*<sup>α</sup>-(arylsulfonyl)-L-arginine amides.

## Enzyme Results and Discussion

*N*<sup>α</sup>-Dansyl-L-arginine *n*-butylamide (3) was the most inhibitory to thrombin of the *N*<sup>α</sup>-dansyl-L-arginine *n*-alkylamides. The less potent inhibition was observed with *n*-alkylamides whose alkyl carbon number was less than three or more than five, such as 1, 2, and 4-6, and other bulky alkyl amides such as 7 and 8. Although this relationship was very similar to that for *N*<sup>α</sup>-dansyl-L-arginine ester derivatives, the effect of the introduction of an *n*-butyl group was more striking in amide derivatives than in ester derivatives. Namely, the effect of the *n*-butylamide was as potent as that of the *n*-butyl ester, with an *I*<sub>50</sub> of 10<sup>-6</sup> M, while ethylamide 1 was 10 times less potent than ethyl ester.<sup>1</sup>

We further investigated the effect of amide derivatives of secondary amines (Table II). *N*-*n*-Butyl-*N*-methylamide 19 retained the high inhibitory potency of *n*-butylamide 3, but *N*-*n*-butyl-*N*-ethylamide 20 and *N*,*N*-di-*n*-butylamide 21 were less inhibitory than *n*-butylamide 3. All of the five- to nine-membered unsubstituted cyclic amide derivatives, 24-28, inhibited thrombin potently with an *I*<sub>50</sub> of 9 × 10<sup>-7</sup> to 3.3 × 10<sup>-6</sup> M. Therefore, we selected a six-membered cyclic amide, piperidine derivative, to investigate the effect of methyl group substitution at the 2, 3, and 4 positions of piperidine on affinity to the enzyme

<sup>a-d</sup> See corresponding footnotes in Table III.

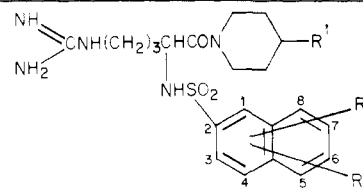

active site. 1-(*N*<sup>α</sup>-Dansyl-L-arginyl)-4-methylpiperidine (31) was found to be the most inhibitory of the methyl-substituted piperidine derivatives, and the inhibitory potency decreased in the order of 3-methylpiperidine 30, 2-methylpiperidine 29. Since the substitution at the 4 position of piperidine afforded the best inhibitor, a series of 4-substituted piperidine derivatives was examined for the thrombin inhibitory effect. 1-(*N*<sup>α</sup>-Dansyl-L-arginyl)-4-ethylpiperidine (32) was more inhibitory than the 4-methylpiperidine derivative 31 and was the best inhibitor of substituted piperidine derivatives. The introduction of other bulky groups to the piperidine ring resulted in a slight decrease in the inhibition potency, with the exception of the 4-phenylpiperidine derivative 37 in which much

less activity was observed. It is of interest that derivatives of 4,4-dimethylpiperidine 33, 4-methylpiperazine 46, and 4-acetyl-piperazine 47 were approximately 10 times less inhibitory than the 4-methylpiperidine derivative 31. *N*<sup>α</sup>-Dansyl-L-arginine amide derivatives of morpholine 40 and thiomorpholine 41, whose molecular size are similar to that of piperidine, were as inhibitory as piperidine derivative 25. Derivatives of indoline 43 and isoindoline 45 were also as inhibitory as 25, although indoline or isoindoline are relatively bulky groups.

Subsequently, we examined the thrombin inhibitory effect of *N*<sup>α</sup>-(arylsulfonyl)-L-arginine derivatives having the typical structures in the carboxamide portion (Tables III and IV). The variation in the thrombin inhibitory effect

due to the variation in the structure of the carboxamide portion was found comparable to that shown in the study of  $N^\alpha$ -dansyl-L-arginine amide derivatives. Amide derivatives of  $N^\alpha$ -(naphthalenesulfonyl)arginine and  $N^\alpha$ -(tetralinsulfonyl)arginine showed  $1/10$  to  $1/30$  and  $1/2$  to  $1/10$  as potent inhibition of thrombin, respectively, than the corresponding amide derivatives of  $N^\alpha$ -dansylarginine, and amide derivatives of 4-methyl- or 4-ethylpiperidine were found the most inhibitory. These results suggest that both the carboxamide portion and the  $N^\alpha$ -substituent portion of arginine derivatives contribute to the binding to thrombin independently.

Therefore, we investigated the effect of the variation in the structure of the  $N^\alpha$ -substituent portion on the thrombin inhibition in arginine derivatives with a carboxamide portion fixed to the amide derivative of 4-methyl- or 4-ethylpiperidine. The substitution at the 5 position, as in 69, 70, 72–74, and 76, but not at the 4 or 8 position, as in

68 and 71, of the naphthalene ring of a  $N^\alpha$ -(naphthalene-1-sulfonyl)arginine derivative resulted in an increase in inhibitory potency (Table V). The introduction of OH (77), CN (78), Cl (79), and NO<sub>2</sub> (80) into the 5 position scarcely influenced the inhibitory potency. These results suggest that the binding affinity does not depend upon the inductive effect of substituents but upon the bulkiness and hydrophobicity of the substituents. The introduction of a carboxyl group (81) resulted in the loss of the inhibitory potency. The negative charge at the 5 position is considered to hinder electrically the binding to thrombin.

The effect of the substitution to a naphthalene ring was further examined with  $N^\alpha$ -(naphthalene-2-sulfonyl)-L-arginine derivatives. The substitution with a methoxy group at the 1, 6, or 7 position (82 and 84–86) increased the inhibitory effect significantly (Table VI), but a substitution at the 4 position, as in 83, did not affect the inhibitory potency of unsubstituted naphthalene derivative 57.

<sup>a-d</sup> See corresponding footnotes in Table III.

However, the remarkable increase in the inhibitory potency was observed with dimethoxy substitution at the 4 and 6 position (88 and 89), whereas in 6,7-dimethoxy substitution (90 and 91) no increase was observed in the inhibitory potency by disubstitution. The derivatives with a methyl or ethyl group at the 6 or 7 position (93–95) also showed the potent inhibitory effect with an *I*<sub>50</sub> at the 10<sup>-7</sup> M level.

Since (tetralinsulfonyl)arginine derivatives were more inhibitory than (naphthalenesulfonyl)arginine derivatives as described above, derivatives with other heterocyclic compounds as the N<sup>α</sup>-substituent were synthesized and examined for their thrombin inhibitory effect. The compounds containing one or two oxygen atoms in a saturated ring decreased the inhibitory potency over 10 times more than the (tetralin-2-sulfonyl)arginine derivative (61 or 62), if the oxygen-containing ring is situated at a terminal end of the compound, like in 98–101 and 106 (Table VII). However, the derivatives with a heterocyclic compound containing oxygen in the ring system in which the oxygen-containing ring is not situated at a terminal end, like in 102–105, showed the potent inhibitory effect with *I*<sub>50</sub> at the 10<sup>-7</sup> M level.

Several compounds with a high inhibitory potency were examined for the susceptibility to hydrolysis by thrombin and trypsin (Table VIII). When incubated with a large amount of thrombin, no compounds tested were hydrolyzed when incubated for 4 h. As for hydrolysis by trypsin,

Table VIII. Hydrolysis of N<sup>α</sup>-Dansyl-L-arginine Amide Derivatives

<sup>a</sup> Values in 4-h incubation. <sup>b</sup> Values in 6-h incubation.

it was observed that *N,N*-disubstituted amide derivatives were not hydrolyzed at all, but *N*-monosubstituted amide derivatives were hydrolyzed only slowly by large amounts of trypsin. Thus, amide derivatives of N<sup>α</sup>-dansyl-L-arginine were found to be strikingly stable toward hydrolysis by thrombin or trypsin in comparison with ester derivatives.

1-(N<sup>α</sup>-Dansyl-L-arginyl)-4-ethylpiperidine has been shown to inhibit thrombin in a competitive manner by the authors<sup>2,5</sup> and recently by others.<sup>6</sup> It has been also shown that its inhibition is highly specific to thrombin and is

### Experimental Section

Melting points were determined on a Yanagimoto micro melting point apparatus and are uncorrected. The results of elemental analyses were within  $\pm 0.4\%$  of the theoretical values. Compounds were checked by IR on a JASCO IR-A2, and the spectral data were consistent with the assigned structure in all cases. TLC was performed on fluorescent silica gel plates (Merck) to a distance of 20 cm with a solvent system of *n*-BuOH-acetic acid-water (3:1:1), and spots were detected under a UV lamp or by exposure to I<sub>2</sub> vapor. The purity of compounds were also checked by high-performance LC (Shimadzu LC-3A) on a Zorbax ODS column (Du pont) with a solvent system of MeOH-water-Pic A (Waters) (65:42:1.5), and peaks were detected by UV (254 nm). In the following, experimental details are presented for typical examples of the synthetic method.

***N*<sup>α</sup>-Dansyl-L-arginine *n*-Butylamide Monohydrate (3).** *N*<sup>α</sup>-Dansyl-L-arginine methyl ester dihydrochloride hydrate (1.0 g, 2.0 mmol) was dissolved in *n*-butylamine (2 mL) with vigorous agitation. After 2 days at room temperature, *n*-butylamine was evaporated in vacuo. The residual syrup was triturated in H<sub>2</sub>O-Et<sub>2</sub>O, filtered, and recrystallized from 50% aqueous MeOH to yield **3** (0.84 g, 90%), mp 150–152 °C.

**1-[*N*<sup>α</sup>-Dansyl-L-arginyl]-4-methylpiperidine Diacetate (31).** **A. Condensation of *N*<sup>α</sup>-(*tert*-Butyloxycarbonyl)-*N*<sup>ω</sup>-nitro-L-arginine (III) with 4-Methylpiperidine.** A solution of III (3.2 g, 10 mmol) and Et<sub>3</sub>N (1.0 g, 10 mmol) in anhydrous THF (40 mL) was cooled to -25 °C and isobutyl chloroformate (1.36 g, 10 mmol) was added. After 15 min, a solution of 4-methylpiperidine (0.99 g, 10 mmol) in anhydrous THF (5 mL) was added and the reaction mixture was maintained at -25 °C for 10 min and then allowed to warm to room temperature for 40 min. The reaction mixture was concentrated under reduced pressure at below 40 °C. The residue was extracted with AcOEt (100 mL), washed (10% aqueous citric acid, saturated NaHCO<sub>3</sub>, and saturated NaCl), dried (Na<sub>2</sub>SO<sub>4</sub>), and evaporated to give 1-[*N*<sup>α</sup>-(*tert*-butyloxycarbonyl)-*N*<sup>ω</sup>-nitro-L-arginyl]-4-methylpiperidine (**IV**; 2.8 g, 70%).

**B. Removal of the *tert*-Butyloxycarbonyl Group and *N*<sup>α</sup>-Sulfonylation with Dansyl Chloride.** Compound **IV** (2.8 g), without further purification, was dissolved in AcOEt (50 mL) containing 10% dry HCl and stirred for 2 h. Cold Et<sub>2</sub>O (50 mL) was added, and the precipitated material, 4-methyl-1-(*N*<sup>ω</sup>-nitro-L-arginyl)piperidine hydrochloride (**V**), was centrifuged and washed with Et<sub>2</sub>O (2 × 20 mL) by successive centrifugation and decantation, the precipitate being well suspended in each wash by vortex mixing. The product was dried in vacuo. To a mixture of **V** (2.1 g, 6.2 mmol) and Et<sub>3</sub>N (1.9 g, 19 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (30 mL) was added dansyl chloride (2.0 g, 7.4 mmol) with stirring at

0–5 °C. After 4 h, the mixture was washed with H<sub>2</sub>O, dried (Na<sub>2</sub>SO<sub>4</sub>), and evaporated. The oily residue was chromatographed on a silica gel column eluting with CHCl<sub>3</sub>-MeOH (97:3). The eluate gave 1-(*N*<sup>α</sup>-dansyl-*N*<sup>ω</sup>-nitro-L-arginyl)-4-methylpiperidine (**VI**; 3.1 g, 95%) as amorphous solids.

**C. Removal of the NO<sub>2</sub> Group.** Compound **VI** (2.0 g, 3.7 mmol) was dissolved in EtOH (20 mL) and AcOH (5 mL), and Palladium black (0.5 g) was added. H<sub>2</sub> was bubbled into the mixture for 2 days at room temperature. After filtering off the catalyst, the filtrate was evaporated to give a viscous oily product. Reprecipitation from MeOH-Et<sub>2</sub>O gave **31** (1.8 g, 80%) as amorphous solids.

**Free 31.** Compound **31** (1.0 g, 1.6 mmol) was dissolved in H<sub>2</sub>O (10 mL) and the pH of the solution was adjusted to pH 11.5 with NaOH. After the solution was stirred for 2 h in an ice bath, the precipitate was collected. Recrystallization from 50% aqueous MeOH gave free **31** (0.75 g, 95%), mp 212 °C (decomposed). Anal. (C<sub>24</sub>H<sub>36</sub>N<sub>6</sub>O<sub>3</sub>S) C, H, N, S.

**1-[*N*<sup>α</sup>-(Anthraquinone-2-sulfonyl)-L-arginyl]-4-ethylpiperidine Hydrogen Fluoride (107).** **V** (3.5 g, 10 mmol), mentioned above, was reacted with anthraquinone-2-sulfonyl chloride in the same manner to give 1-[*N*<sup>α</sup>-(anthraquinone-2-sulfonyl)-*N*<sup>ω</sup>-nitro-L-arginyl]-4-ethylpiperidine (4.7 g, 81%) as amorphous solids. Then this was dissolved in anhydrous HF (2 mL) and anisole (0.5 mL) at 0 °C. After 30 min, HF was evaporated in vacuo below 5 °C. The residue was washed with dry Et<sub>2</sub>O (5 × 10 mL) by successive centrifugation and decantation. The product was dried in vacuo. Reprecipitation from EtOH-Et<sub>2</sub>O gave pure **107** (2.9 g, 65%) as amorphous solids.

**Inhibition Studies of the Clotting Activity of Thrombin.** The method has been described in the preceding paper.<sup>1</sup>

**Hydrolysis Study by Thrombin and Trypsin.** The reaction mixture containing 1 mM test compounds, 0.1 M Tris-HCl buffer (pH 8.0), and 100 units of thrombin or 0.15 mg of trypsin in a total volume of 1.0 mL was incubated at 37 °C. An aliquot of sample was taken out periodically and spotted on a silica gel thin-layer sheet (Kodak) and developed with ethanol-chloroform (1:1). Fluorescence intensity of the spots of *N*<sup>α</sup>-dansyl-L-arginine and amides of *N*<sup>α</sup>-dansyl-L-arginine on the chromatogram was estimated visually under UV light.

**Acknowledgment.** The authors thank M. Sugano, T. Shirasaka, A. Maruyama, Mrs. K. Sugano, and A. Sugiyama for their technical assistance and Dr. S. Hattori, General Manager of Biosciences Laboratory, Central Research Laboratories, Mitsubishi Chemical Industries Limited, for his valuable advice and encouragement throughout the work. We are also indebted to members in Systems Engineering Laboratory, Central Research Laboratories, Mitsubishi Chemical Industries Limited, for elemental analyses.
