Received November 20, 1992

A series of substituted 8-styryl derivatives of 1,3,7-alkylxanthines was synthesized as potential A_2 -selective adenosine receptor antagonists, and the potency at rat brain A_1 - and A_2 -receptors was studied in radioligand binding experiments. At the xanthine 7-position, only small hydrophobic substituents were tolerated in receptor binding. 7-Methyl analogues were roughly 1 order of magnitude more selective for A_2 versus A_1 receptors than the corresponding 7-H analogues. 1,3-Dimethylxanthine derivatives tended to be more selective for A_2 -receptors than the corresponding 1,3-diallyl, diethyl, or dipropyl derivatives. Substitutions of the phenyl ring at the 3-(monosubstituted) and 3,5-(disubstituted) positions were favored. 1,3,7-Trimethyl-8-(3-chlorostyryl)xanthine was a moderately potent (K_i vs [3 H]CGS 21680 was 54 nM) and highly A_2 -selective (520-fold) adenosine antagonist. 1,3,7-Trimethyl-8-[3-[(3-carboxy-1-oxopropyl)amino]styryl]xanthine was highly A_2 -selective (250-fold) and of enhanced water solubility (max 19 mM). 1,3-Dipropyl-7-methyl-8-(3,5-dimethoxystyryl)xanthine was a potent (K_i = 24 nM) and very A_2 -selective (110-fold) adenosine antagonist.

Introduction

Adenosine acting through the A_2 -receptor subtype elicits a range of physiological responses, including the inhibition of platelet aggregation¹ dilation of blood vessels,² erythropoietin production,³ and depression of locomotor activity.⁴ The second messenger system invariably associated with the A_2 -receptor is the stimulation of adenylate cyclase, while the A_1 -receptor has been found to be coupled to a number of second messenger systems, including inhibition of adenylate cyclase, inhibition of calcium entry, stimulation of potassium flux, and effects on phosphoinositide metabolism.⁵

All of the adenosine agonists yet reported are derivatives of adenosine, but many classes of adenosine antagonists are known.⁵ The earliest examples of adenosine antagonists are the naturally-occurring xanthines, e.g. caffeine and theophylline, which are nonselective for adenosine receptor subtypes and have phosphodiesterase inhibitory effects as well.⁶ While thousands of ligands selective for A₁ receptors have been synthesized, it is only recently that A₂-selective agonists and antagonists have been reported.^{2,7-11} Certain 2-substituted adenosine² and adenosine-5'-carboxamide derivatives⁸ are A₂-selective agonists. Several xanthine derivatives, most notably, simple caffeine derivatives bearing a 1-propargyl group (1, Figure 1),^{6,7} and those doubly substituted by 7-methyl and 8-cycloalkyl

Figure 1. Xanthine and non-xanthine derivative having either high affinity or some selectivity for A_2 -adenosine receptors.

groups (2), 10,11 have been reported to be A₂-selective in binding and/or adenylate cyclase experiments. A number of non-xanthine derivatives have been found to be weakly selective for A₂-receptors, e.g. the triazoloquinazoline CGS 15943 (3), 12 the triazoloquinoxaline CP66,713 (4), 13 and a series of imidazotriazinones, including M216765 (5). 14

It would be highly desirable to have a general, high affinity A₂-antagonist probe for receptor characterization. At this time, several 8-phenylxanthines, such as XAC, 6, may serve as radioligands at striatal A₂-receptors, but this high-affinity binding is limited to certain species in which XAC is not A₁-selective. ¹⁵ Shimada et al. ¹¹ have reported that 1,3,7-alkylxanthine derivatives substituted with 8-styryl groups, particularly 3,4-dimethoxy and 3,4,5-trimethoxy, act as selective A₂-antagonists. In this study

we have further explored the structure-activity relationships of 8-styrylxanthines at adenosine receptors.

Results

Chemistry. 8-Styrylxanthine derivatives, substituted at the 1-, 3-, and 7-xanthine positions and at the α - and phenyl positions of the styryl moiety were synthesized according to the routes shown in Figures 2 and 3. The structures of compounds 15-56 and the affinities in radioligand binding assays at rat brain A_1 - and A_2 -receptors are given in Table I. Small alkyl substituents at the 1- and 3-positions were identical and varied from methyl to propyl. Substituents at the 7-position varied from H to 2-phenylethyl. A number of related xanthines (not 8-styryl) were prepared for comparison (Table II). The physical characteristics of the xanthine derivatives are summarized in Table III.

A trans-cinnamic acid, 8 (Figure 2), was condensed with a 1,3-dialkyl-5,6-diaminouracil, 7. The resulting amide, 9, was cyclized under strongly basic conditions to give the xanthine derivative 10. The intermediate cinnamic acids were obtained from commercial sources or prepared as described in the Experimental Section. After formation of the 7-H xanthine derivative 10, methylation using methyl iodide at 50 °C was carried out. The trans orientation of the 8-styryl group was verified for each of the derivatives based on the proton-proton coupling constants of the olefinic protons (typically \geq 15 Hz). In the case of compound 16 (α -fluoro), the fluorine-proton coupling constant was found to be 37 Hz, consistent with the trans configuration. 16

Synthesis of hydroxyl ring-substituted 8-styrylxanthines was attempted by the usual route (Figure 2), starting with

the 3- or 4-hydroxycinnamic acid. The intermediate amide was formed in low yield, and cyclization provided the desired xanthine in only very low yield (e.g. 18). Carrying out the sequence with hydroxyl protection in order to obtain a free hydroxyl group in the para position of the final product was attempted, but proved unsatisfactory. Acetyl ester and p-methoxybenzyl ether derivatives formed the amide intermediate 9, but the cyclization step in 4 N NaOH failed. The attempted deprotection of monomethoxy derivatives in the series using sodium thiophenolate, trimethylsilyl iodide, or nitrogen bases at high temperature was unsuccessful. It was however possible to selectively demethylate the p-methoxy of 8-(3.4.5trimethoxy)styrylxanthines, 12 (Figure 3), using sodium thiophenolate in DMF at 160 °C. The position of the free hydroxyl group (4) in 13 was determined by proton NMR. This hydroxyl group could be readily acylated or alkylated (in some cases carried out in situ following the deprotection reaction) to provide 14.

Aryl amino substituents were obtained via Zn/HOAc reduction of the corresponding nitro derivative (e.g. 21) or in the case of tertiary aniline (e.g. 30a), by direct incorporation of the corresponding cinnamic acid. The N-7 position of 30a was selectively alkylated using methyl iodide at 50 °C to provide 30b. Catalytic hydrogenation of the nitrostyryl derivative 21 afforded the saturated aniline analogue 57.

Biological Evaluation. Binding assay. The analogs were tested in a radioligand binding assay for affinity at adenosine receptors in rat brain membranes. The compounds were assayed for affinity at rat A_1 cortical receptors using [3 H]- N^6 -(2-phenylisopropyl)adenosine 17 and at rat striatal A_{2a} receptors using [3 H]CGS 21680 (Tables I and II). 8 K_i values of nearly 10^{-8} M at A_2 -receptors and selectivities of hundreds of fold were achieved.

Several sites on the xanthine molecule have been varied. The N-1 and N-3 positions have been substituted with small alkyl groups (C_1 – C_3). In all cases, substituents at the 1- and 3-positions are identical. The greatest effect of elongating NMe to NPr groups at these positions was a substantial increase in A_1 -affinity, thus diminishing A_2 -selectivity. A 1,3-diethyl-7-methylxanthine, 45b, was nearly as A_2 -selective (44-fold) as the 1,3-dimethyl analogue, 44b, which was 70-fold selective. The corresponding diallyl analogue, 46 (reported previously¹¹ to be >6700 A_2 -selective), was only 13-fold selective in rat brain in this study.

The N-7 position is either unsubstituted or substituted with groups as large as 2-phenylethyl (compound 44f). Only small, hydrophobic groups (including ethyl and propargyl) at this position were tolerated in binding to either receptor. The 7-methyl analogues were found to exhibit the greatest degree of A2-selectivity. Figures 4 and 5 show correlations of affinity for the 7-H to 7-Me modification, which generally results in decreased A₁affinity and increased A2-affinity. In general, among 8-styrylxanthine derivatives, the 1,3,7-trimethylxanthines were A₂-selective by factors between 10- and 500-fold, whereas the corresponding 1.3-dimethylxanthines were generally A₂-selective by factors of only 2-6-fold. The 7-(hydroxyethyl) and phenylethyl substituents (45d and 45f) were nearly inactive, in addition to having less favorable aqueous solubility. In the 1,3-dipropyl series (Figure 5), each 7-H analogue was relatively nonselective. The selectivity of the 1,3-dipropyl-7-methyl-8-styrylxanthines (resulting from decreased A₁-affinity upon methylation) was highly dependent on the styryl substitution.

The effects of substitution of the 8-styryl group could be compared within the 1,3-dimethyl series and within the 1,3,7-trimethyl series. The unsubstituted styryl analogue 15a (7-H) was nonselective, but was moderately selective (41-fold) following methylation (15b). Fluorine substitution in the α -position resulted in diminished potency at both A₁- (3-fold) and A₂-receptors (7-fold). Monomethoxy substitution of the phenyl ring (compounds 17, 19, and 29) resulted in selectivity of 18-63-fold in the 7-Me series, but did not result in significant A₂-selectivity in the 7-H series. Compound 19b, the meta derivative, was the most potent and selective monomethoxy derivative, with a K_i value of 85 nM at A₂-receptors. The analogue bearing a 3-hydroxystyryl group in the 7-H series. 18. was equipotent with the methoxy compound 19a at A_2 -receptors and more potent at A_1 -receptors.

The A₂-potency of 1,3,7-trimethylxanthines having a variety of styryl 3-position substituents varied in the order: acetylamino > chloro, amino > fluoro, methoxy > H > trifluoromethyl > nitro. Although the 3-chloro derivative (28, K; value of 54 nM) was slightly less potent than the 3-acetylamino derivative (23, K_i value of 39 nM, 240-fold selective) it was more selective (520-fold). It was equipotent to the amino derivative 22b, but considerably more selective. Very bulky substituents at the 3-position (urethanes 25 and 26) reduced potency at A2-receptors roughly 20-fold, but moderate A₂-selectivity remained. A water-solubilizing 3-[(3-carboxy-1-oxopropyl)amino] group (24) resulted in decreased potency (134 nM) but high selectivity (250-fold).

For comparison to the methoxy group at the styryl 4-position, a highly electron-donating group, e.g. dimethylamino, was incorporated and resulted in greatly diminished potency at both receptors. Only the 7-Me form, 30b, displayed A₂-selectivity.

Dimethoxy substitutions at various positions of the phenyl ring were compared, and substantial differences were observed. The order of both potency and selectivity was 3.5 > 3.4 > 2.3. In the 1,3,7-trimethyl series, 3,5dimethoxy or 3,5-difluoro substituents (33b and 34b, respectively) resulted in >200-fold selectivity.

In the 1.3-dipropyl-7-methyl series, A₂-selectivity was generally merely 5-19-fold, with only one exception (53b). The 3-chlorostyryl analogue 51b, analogous to the most selective agent in the 1,3,7-trimethyl series, was only 14fold selective. 1.3-Dipropyl-7-methyl-8-(3.5-dimethoxystyryl) xanthine, 53b, proved to be a potent $(K_i \text{ vs } [^3\text{H}]\text{CGS})$ 21680 was 24 nM) and A2-selective (110-fold) adenosine antagonist, i.e. 5-fold more selective than the corresponding 3,4-dimethoxy analogue, 52b. Compound 52b was prepared by Shimada et al. [KF17837]¹¹ and was reported to be 190-fold selective, versus 19-fold in this study.

High selectivities were also observed among 1.3.7trimethylxanthines that were trisubstituted on the phenyl ring. 1,3,7-Trimethyl-8-(3,4,5-trimethoxy)styrylxanthine, 44b, was 70-fold A2-selective in binding in the rat brain (vs >5600-fold reported by Shimada et al.11). The corresponding 1,3-dimethyl analogue 44awas only 6-fold A2-selective. In general, the order of both potency and selectivity for trisubstituted phenyl substituents was 3,4,5 > 2,3,4 > 2,4,5. Among 3,4,5-substituted analogues there was considerable substitution of the 4-methoxy group tolerated at A2-receptors. The moderately selective 3,5-

dimethoxy-4-hydroxy analogue, 35, was acylated (36) and alkylated (37, 38), resulting in enhanced A₂-selectivity and potency. The 4-acetoxy-3,5-dimethoxy analogue, 36, was 93-fold A2-selective. Functional groups that also tended to increase water solubility, such as alkylamines (38 and 40), were included. These amino derivatives may serve as functionalized congeners 20 since it appears that long chain extension is possible without disrupting receptor binding. Moderately potent and selective acylated derivatives (39, 41, and 42) were prepared from the amine functionalized congeners. Butyl versus trans-butenylamine congeners were compared to examine the effect of altering conformational flexibility at this distal site. No major differences in potency or selectivity between butyl (e.g. 38) and butenyl (e.g. 40) analogues were found.

In an attempt to account for the discrepancy in K_i values between the present study and Shimada et al. 11, the effects of varying concentrations of DMSO in the assay medium were examined. DMSO was needed because of the limited aqueous solubility (in the range of 10⁻⁵ M) of most of the 8-styrylxanthines tested. To avoid precipitation associated with serial aqueous dilutions, the only point at which xanthine dissolved in DMSO was added to aqueous medium was directly into the incubation tube. We examined the effects of varying concentrations of DMSO (ranging from 0.5 to 6%) on the apparent affinity of compound 53b (Figure 6A). The apparent affinity of compound 53b at A2 receptors was constant within the range of 0.5-6% DMSO. In addition, the total specific binding of [3H]CGS 21680 to striatal membranes was maintained, even at 6% DMSO. However, A₁-affinity appeared to be somewhat dependent on DMSO concentration (at 0.5 and 1% DMSO), and at 6% DMSO the total specific binding of [3H]PIA (data not shown) diminished to roughly 30% of its value at 1% DMSO. At the lowest concentration (0.5% DMSO), higher concentrations of the drug were required to displace [3H]PIA. This effect of increase in the apparent K_i value at $\leq 1\%$ DMSO most likely relates to the xanthine precipitating from the solution, since the UV absorption (Figure 6B) does not increase in a linear fashion with the amount of xanthine added to a fixed aqueous volume. The UV absorption decreases beyond 20 µM, suggesting supersaturation.

Related, non-styrylxanthines (Table II) were tested in adenosine receptor binding for comparison to the 8-styryl derivatives. Cyclohexylcaffeine, 2, which was found to beA₂-selective in effects on adenylate cyclase¹⁰ was nonselective in binding. The saturated aniline derivative 57 was ~ 300 -fold less potent at A_2 receptors than the corresponding styryl derivative 22b. Ring-constrained styryl analogues, 58, containing a 8-(2-benzofuran) group were synthesized. Both the 7-H and 7-Me analogues were only weak antagonists of binding at adenosine receptors (Table II).

Discussion

Potent and A₂-selective adenosine antagonists, suitable as pharmacological tools, have long been lacking. A2selective antagonists may also have application as therapeutic agents, e.g. in the treatment of Parkinson's disease.²⁴ The nonselective non-xanthine antagonist CGS 15943, 3, was under development as an antiasthmatic.²⁵

It was only recently that 8-styrylxanthines were reported as the first potentially useful compounds by Shimada et

al. These authors found that 8-styryl derivatives of 1,3dimethylxanthines were the most selective for A2-receptors (selectivities greater than 5000-fold were reported), but the affinities of the corresponding 1,3-propyl analogues at both subtypes were greater (the most potent compound having a K_i value of 7.8 nM at A_2 receptors).

The selectivity factors in the present study were generally much less than those reported by Shimada et al.11 The principal reason may be that A₁-affinity in this study was measured in the same species as A2-affinity (rat), whereas Shimada et al. measured A₁ affinity in guinea pig brain and A2 affinity in rat brain. The species dependence of affinity of alkylxanthines at both A1 and A_{2a} receptors is well-documented.^{21,22} Invariably, the affinity of xanthines at A₁-receptors is higher in the rat than in the guinea pig, but the interspecies affinity ratios have been found to vary from only 2-fold for theophylline to as much as 20-fold for 8-phenyltheophylline.21 Indeed, the reported variation in A₁-affinities for 8-styrylxanthines in different species differ even more: up to 33-fold (e.g. compound 47 has an A₁-affinity in rat of 55 nM versus 1800 nM in guinea pig;11 Erickson et al.19 have determined a K_i value at rat A_1 -receptors of 22 nM). Thus, comparing guinea pig A_1 -values to rat A_2 -affinities results in artificially high selectivity ratios, and we therefore feel strongly that affinities should be compared within one species in order to yield useful figures.

In addition, some unexplained and substantial differences (e.g. compound 50a) were observed between K_i values versus [3H]CGS 21680 in this study and versus [3H]NECA in the study of Shimada et al. 11 (both having been measured in rat striatal membranes).

Another potential reason for discrepancies with previous results in binding assays was the amount of DMSO present. Shimada et al. 11 utilized approximately 1% DMSO in the assay medium, and we used 2%. We demonstrated (Figure 6) that at 0.5% DMSO a 1,3-dipropyl-7-methylxanthine derivative, 53b, did not remain dissolved in aqueous solution at concentrations greater than $10 \,\mu\text{M}$. This would affect in particular A₁-displacement curves for many compounds in this study, for which data points beyond xanthine concentrations of 10 μ M are required. Thus, the addition of insufficient DMSO to the medium (or serial aqueous dilutions) might tend to overestimate the selectivity of the A2-selective xanthines, but would not be expected to alter the apparent affinity at A₂ receptors (Figure 6A).

Functional studies, for example to characterize the antagonism of adenosine agonist-elicited increases in cyclic AMP, will be an important component of future work with these xanthine derivatives.

The most significant findings in this study are as follows: (1) the position of styryl ring substitution (meta favored) is a determinant of potency and selectivity (compare 17b, 19b, and 29b), (2) increasing the size of small alkyl groups at the 1- and 3-xanthine position (e.g. 45b versus 44b) increases potency at both receptors and decreases A₂-selectivity, and (3) A₂-selectivity and moderate affinity are maintained with long chain extension from the para position of the styryl ring (e.g. 41). It would seem that this position of the 8-styryl group when bound to the receptor is located in a relatively insensitive region. This finding is not unexpected given previous similar observations for para-substituted 8-phenylxanthines. 20 A2-Selectivities of thousands of fold reported previously¹¹ were not observed in this study, although the selectivities of up to 520-fold (compound 28), promise to be useful in physiological studies. A2-Antagonists of particular interest are compounds 23, 24, 27b, 28, 33b, and 34b (A_2 -selectivity of 200-fold or greater); compounds 23, 28, 49, 50b, 52b, 53b, and 54b (A₂-affinity 50 nM or less); and compounds 22b, 38, and 40 (amine functionalized congeners). Compound 24 also has enhanced water solubility; the maximal solubility in a 0.1 M potassium phosphate solution at pH 7.4 was 19 mM.

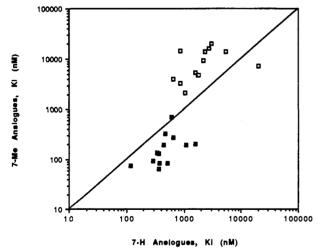

Figure 4. Correlation of affinity at adenosine receptors for 7-H versus 7-Me analogues of 1,3-dimethyl-8-styrylxanthine derivatives. Inhibition constants in nM given for A_1 -receptors (\square) and A_2 -receptors (\square).

A goal of this study is to identify adenosine antagonists that may be utilized as radioligands. Compound 53b is of sufficiently high affinity and A_2 -selectivity to be useful in binding assays when radiolabeled. An additional objective is to design functionalized congeners for eventual

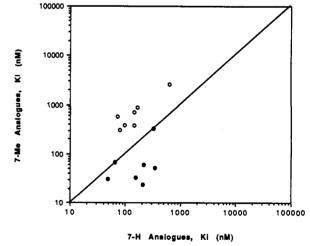

Figure 5. Correlation of affinity at adenosine receptors for 7-H versus 7-Me analogues of 1,3-dipropyl-8-styrylxanthine derivatives. Inhibition constants in nM given for A_1 -receptors (\bigcirc) and A_2 receptors (\bigcirc).

covalent labeling of the receptor, as was carried out for A_2 receptors using an agonist ligand²³ and for A_1 -receptors.²⁰ The arylamino derivatives **22b** and **49** and the alkylamino derivatives **38** and **40** are chemically functionalized for further reaction leading to A_2 -selective conjugates.

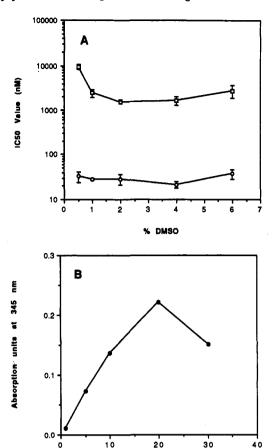

Figure 6. (A) Dependence of observed IC₅₀ values on DMSO $concentration in competitive \ radioligand \ binding \ of \ 1,3-dipropyl-$ 8-(3.5-dimethoxystyryl)xanthine, 53b, at A_1 - and A_2 -receptors. IC_{50} values are expressed in nM (mean \pm SEM for three or more determinations) vs [3H]PIA (1 nM) at rat A1-receptors (\square) and vs [3H]CGS21680 (5 nM) at rat striatal A2-receptors (O). (B) UV absorption of water solutions following addition of compound 53b dissolved in DMSO (theoretical final concentration assuming complete dissolution given on abscissa). The final concentration of DMSO was 0.5% in each case. The peak absorption occured at 345 nm, with a molar extinction coefficient (ϵ) of 13 200.

Theoretical concentration (µM)

Experimental Section

Chemistry. New compounds were characterized (and resonances assigned) by 300-MHz proton nuclear magnetic resonance spectroscopy using a Varian GEMINI-300 FT-NMR spectrometer. Unless noted, chemical shifts are expressed as ppm downfield from tetramethylsilane. Synthetic intermediates were characterized by chemical ionization mass spectrometry (NH₃) and xanthine derivatives by fast atom bombardment mass spectrometry (positive ions in a glycerol matrix) on a JEOL SX102 mass spectrometer. In the EI mode accurate mass was determined using a VG7070F mass spectrometer. C, H, and N analyses were carried out by Atlantic Microlabs (Norcross, GA), and $\pm 0.4\%$ was acceptable. All xanthine derivatives were judged to be homogeneous using thin-layer chromatography following final purification. 7-Methoxy-2-benzofurancarboxylic acid, transcinnamic acid, and the following derivatives thereof were purchased from Aldrich (St. Louis, MO): α-fluoro, 2-methoxy, 3,4-dimethoxy, 3,5-difluoro, and 3,5-dimethoxy. 3- and 4-methoxy derivatives of trans-cinnamic acid were purchased from Fluka (Ronkonoma, NY). The following derivatives of trans-cinnamic acid were purchased from Lancaster (Windham, NH): 2,3dimethoxy, 3,4,5-trimethoxy, 2,3,4-trimethoxy, 2,4,5-trimethoxy, and 3-fluoro. The following derivatives of trans-cinnamic acid were from Janssen Chimica (Geel, Belgium): 3-trifluoromethyl, 3-chloro, and 3-nitro. 2-Chloroadenosine was purchased from Research Biochemicals, Inc. (Natick, MA). Compound 46 was the gift of Dr. Ray Olsson (University of Southern Florida, Tampa, FL). 8-Cyclohexylcaffeine, 2, was the gift of Dr. John W. Daly (NIH). Analytical TLC plates and silica gel (230-400 mesh) were purchased from VWR (Bridgeport, NJ).

Synthesis of Xanthine Derivatives. General Procedure A: Reaction of Substituted Cinnamic Acid Derivatives with 5,6-Diamino-1,3-dimethyluracil To Yield Amide 9. The substitued cinnamic acid (1 equiv) was dissolved in a minimum volume of DMF containing 1,3-dialkyl-5,6-diaminouracil (1.5 equiv). 1-[3-(Dimethylamino)propyl]-3-ethylcarbodiimide hydrochloride (1 equiv) was added, followed by a catalytic amount (0.05 equiv) of 4-(N,N-dimethylamino)pyridine and 0.05 equiv of imidazole. The mixture was stirred at room temperature for 3 h, and saturated sodium chloride solution was added (for 1,3dipropyl derivatives water was used here), to form a precipitate or amorphous insoluble fraction. The insoluble residue was filtered and dissolved in 4 N aqueous sodium hydroxide containing sufficient methanol to obtain a clear solution.

The mixture was heated at 60 °C for 2 h or until the complete disappearance of starting material, as judged using TLC (silica plate, CHCl₃/CH₃OH/HOAc, 85:10:5, v/v). The mixture was cooled and acidified to pH = 1 with 6 N aqueous hydrochloric acid solution.

The precipitate was washed with water, dried, and further purified using a preparative silica plate (85-95% CHCl₃/5-15% methanol/1-5% HOAc). This procedure was used to make compounds 17a, 29a, 32a, 33a, etc.

General Procedure B: Methylation of N-7 8-Styrylxanthines. An 8-styrylxanthine derivative (1 equiv) was dissolved in a minimum of DMF. Excess finely powdered anhydrous potassium carbonate was added and the solution was left in an ultrasonic bath for 10 min. Methyl iodide (5 equiv) was added. The mixture was stirred at 60 °C for 30 min or until the complete disappearance of starting material, as judged using TLC (silica, chloroform/methanol/acetic acid, 95:4:1, v/v). The reaction mixture was cooled, and excess concentrated aqueous ammonia solution was added. The precipitate was washed with water, dried in vacuo, and further purified either by crystallization or by chromatography on a preparative thin-layer plate (85-95% chloroform/5-15% methanol/1-5% acetic acid). This procedure was used to make compounds 17b, 29b, 32b, 33b, etc.

1,3-Dimethyl-8-(2-methoxystyryl)xanthine (17a). Compound 17a was made from 2-methoxycinnamic acid according to general procedure A and triturated with hot methanol: Mp: >300 °C. ¹H NMR DMSO- d_6 : δ 3.27 (s, 3 H, N₃-CH₃), 3.35 (s, 3 H, N_1 -CH₃), 3.5 (s, 3 H, OCH₃), 3.9 (s, 3 H, N_7 -CH₃), 7.1 (d, 1 H, J = 18 Hz), 7.0-7.2 (m, 2 H), 7.4 (m, 1 H), 7.7 (d, 1 H, J = 8 Hz), 7.8 (d, 1 H, J = 18 Hz). MS (CI/NH₃): m/e 313 (MH⁺, base) 281, 117.

1,3,7-Trimethyl-8-(2-methoxystyryl)xanthine (17b). Compound 17b was made from 17a according to general procedure B. Mp: 238-240 °C. ¹H NMR DMSO-d₆: δ 3.24 (s, 3 H, N₃-CH₃), 3.48 (s, 3 H, N₁-CH₃), 3.90 (s, 3 H, OCH₃), 4.06 (s, 3 H, N_7 -CH₃), 7.0-7.14 (m, 2 H), 7.34 (d, 1 H, J = 16 Hz), 7.4 (m, 1 H), 7.9 (d, 1 H, J = 8 Hz), 8.0 (d, 1 H, J = 16 Hz). MS (CI/NH₃): m/e 327 (MH⁺) base peak.

1,3-Dimethyl-8-[3-(trifluoromethyl)styryl]xanthine (20a). Compound 20a was made from 3-(trifluoromethyl)cinnamic acid according to general procedure A. Mp: >300 °C. ¹H NMR DMSO- d_6 : δ 3.26 (s, 3 H, NCH₃), 3.48 (s, 3 H, NCH₃), 7.19 (d, 1 H, J = 16 Hz), 7.64 (t, 1 H, J = 8 Hz), 7.70 (d, 1 H, J = 7 Hz), $7.72 \, (d, 1 \, H, J = 16 \, Hz), 7.94 \, (d, 1 \, H, J = 8Hz), 7.96 \, (s, 1 \, H).$ MS (CI): m/e 350 (base), 329, 292.

1.3.7-Trimethyl-8-[3-(trifluoromethyl)styryl]xanthine (20b). Compound 20b was made from 20a according to general procedure B. Mp: 232-236 °C. ¹H NMR DMSO-d₆: δ 3.25 (s, 3 H, NCH₃), 3.49 (s, 3 H, NCH₃), 4.09 (s, 3 H, N₇-CH₃), 7.58 (d, 1 H, J = 16 Hz), 7.67 (t, 1 H, J = 8 Hz), 7.72 (d, 1 H, J = 8 Hz),7.78 (d, 1 H, J = 16 Hz), 8.09 (d, 1 H, J = 7 Hz), 8.26 (s, 1 H).MS (EI): m/e 364.

1,3-Dimethyl-8-(3-nitrostyryl)xanthine (21a). Compound 21a was made from 3-nitrocinnamic acid according to general procedure A (temperature raised to 80 °C for 3 h, recrystallized from methanol). Mp: >300 °C. ¹H NMR DMSO- d_6 : δ 3.25 (s, 3 H, NCH₃), 3.48 (s, 3H, NCH₃), 7.22 (d, 1 H, J = 16 Hz), 7.70 (t, 1 H, J = 8 Hz), 7.76 (d, 1 H, J = 16 Hz), 8.10 (d, 1 H, J = 8) Hz), 8.18 (d, 1 H, J = 8 Hz), 8.41 (s, 1 H). MS (EI): m/e 327 (base), 310, 280.

1,3,7-Trimethyl-8-(3-nitrostyryl)xanthine (21b). Compound 21b was made from 21a according to general procedure B. Mp: 306-308 °C. ¹H NMR DMSO- d_6 : δ 3.23 (s, 3 H, NCH₃), 3.47 (s, 3 H, NCH₃), 4.08 (s, 3 H, N₇-CH₃), 7.63 (d, 1 H, J = 16 Hz), 7.71 (t, 1 H, J = 8 Hz), 7.80 (d, 1 H, J = 16 Hz), 8.18 (d, 1 H, J = 8 Hz), 8.23 (d, 1 H, J = 8 Hz), 8.70 (s, 1 H). MS (EI): m/e 341 (base), 294.

1,3-Dimethyl-8-(3-aminostyryl) xanthine (22a). Compound 22a was made from 21a by reducing with Zn/acetic acid for 3 h. Mp: >300 °C. 1 H NMR DMSO- 1 C 6.56 (d, 1 H, 1 J = 8 Hz), 3.46 (s, 3 H, NCH₃), 5.19 (s, 2 H, NH₂), 6.56 (d, 1 H, 1 J = 8 Hz), 6.74 (d, 1 H, 1 J = 8 Hz), 6.76 (s, 1 H), 6.84 (d, 1 H, 1 J = 16 Hz), 7.05 (t, 1 H, 1 J = 8 Hz), 7.49 (d, 1 H, 1 J = 16 Hz). MS (CI/NH₃): 1 M/e 315 (M + NH₄+), 298 (MH+, base).

1,3,7-Trimethyl-8-(3-aminostyryl)xanthine (22b). Compound 22b was made from 21b using Zn/acetic acid as reducing agent for 3 h. Mp: 222-224 °C. ¹H NMR DMSO- d_6 : δ 3.22 (s, 3 H, N-CH₃), 3.46 (s, 3 H, NCH₃), 4.00 (s, 3 H N₇-CH₃), 5.14 (s, 2 H, NH₂), 6.58 (d, 1 H, J = 8 Hz, H-4), 6.87 (s, 1 H, H-2), 6.92 (d, 1 H, J = 8 Hz, H-6), 7.07 (t, 1 H, J = 8 Hz, H-5), 7.14 (d, 1 H, J = 16 Hz), 7.51 (d, 1 H, J = 16 Hz). MS (CI/NH₃): m/e 312 (MH⁺).

1,3,7-Trimethyl-8-[3-(acetylamino)styryl]xanthine (23). Compound 23 was made from 22b with acetic anhydride in DMF and DMAP for 1 h. Mp: >300 °C. ¹H NMR DMSO- d_6 : δ 2.06 (s, 3 H, COCH₃), 3.23 (s, 3 H, NCH₃), 3.47 (s, 3 H, NCH₃), 4.03 (s, 3 H, N₇-CH₃), 7.24 (d, 1 H, J = 16 Hz), 7.34 (t, 1 H, J = 8 Hz), 7.50 (t, 1 H, J = 8 Hz), 7.54 (d, 1 H, J = 8 Hz), 7.61 (d, 1 H, J = 16 Hz), 7.86 (s, 1 H). MS (CI/NH₃): m/e 354 (MH⁺).

1,3,7-Trimethyl-8-[3-[(3-carboxy-1-oxopropyl)amino]-styryl]xanthine (24). Compound 24 was made from 22b with succinic anhydride in DMF and DMAP. Mp: >300 °C. ¹H NMR DMSO- d_6 : δ 2.28 (t, 2 H, J = 7 Hz), 2.43 (t, 2 H, J = 7 Hz), 3.23 (s, 3 H, NCH₃), 3.47 (s, 3 H, NCH₃), 4.03 (s, 3 H, N₇CH₃), 7.24 (d, 1 H, J = 16 Hz), 7.32 (t, 1 H, J = 8 Hz), 7.45 (d, 1 H, J = 8 Hz), 7.54 (d, 1 H, J = 8 Hz), 7.61 (d, 1 H, J = 16 Hz), 7.82 (s, 1 H). MS (CI/NH₃): m/e 394 (M - OH), 312, 209 (base). UV: λ_{max} (methanol) 349 nm, $\log \epsilon$ = 4.48. The maximal aqueous solubility following dissolution in K₂HPO₄ (0.1 M) was determined to be 19 mM.

1,3,7-Trimethyl-8-[3-[(tert-butyloxy)carbonyl]amino]-styryl]xanthine (25). Compound 25 was made from 22b with di-tert-butyl dicarbonate and DMAP in DMF. Mp: >300 °C. 1 H NMR DMSO- d_6 : δ 1.40 (s, 9 H, CH₃COO), 3.17 (s, 3 H, NCH₃), 3.41 (s, 3 H, NCH₃), 3.89 (s, 3 H, N₇-CH₃), 7.23 (d, 1 H, J = 16 Hz), 7.33 (d, 1 H, J = 8 Hz), 7.51 (t, 1 H, J = 8 Hz), 7.57 (s, 1 H), 7.67 (d, 1 H, J = 16 Hz), 7.75 (d, 1 H, J = 8 Hz). MS (CI/NH₃): m/e 414 (M - CH₃ + NH₄+, base), 338, 314, 312.

1,3,7-Trimethyl-8-[3-[bis](tert-butyloxy)carbonyl]amino]-styryl]xanthine (26). Compound 26 was made from 22b with di-tert-butyl dicarbonate and DMAP in DMF. Mp: 175-177 °C. ¹H NMR DMSO- d_6 : δ 1.39 (s, 18 H, CH₃COO), 3.23 (s, 3 H, NCH₃), 3.46 (s, 3 H, NCH₃), 4.03 (s, 3 H, N₇-CH₃), 7.17 (d, 1 H, J = 8 Hz), 7.42 (t, 1 H, J = 8 Hz), 7.43 (d, 1 H, J = 16 Hz), 7.67 (d, 1 H, J = 16 Hz), 7.69 (d, 1 H, J = 8 Hz), 7.74 (s, 1 H). MS (CI/NH₃): m/e 514 (M - CH₃ + NH₄+), 414 (base).

1,3-Dimethyl-8-(4-methoxystyryl)xanthine (29a). Compound 29a was made from 4-methoxycinnamic acid according to general procedure A. Mp: >320 °C. ¹H NMR DMSO- d_6 : δ 3.24 (s, 3 H, N₃-CH₃), 3.46 (s, 3 H, N₇-CH₃), 3.78 (s, 3 H, OCH₃), 6.85 (d, 1 H, J = 16 Hz), 7.0 (d, 2 H, J = 8 Hz), 7.55 (d, 2 H, J = 8 Hz), 7.6 (d, 1 H, J = 16 Hz). MS (CI/NH₃): m/e 313 (MH⁺, base) 172.

1,3,7-Trimethyl-8-(4-methoxystyryl)xanthine (29b). Compound 29b was made from 29a according to general procedure B. Mp: >320 °C. ¹H NMR DMSO- d_6 : δ 3.22 (s, 3 H, N₃CH₃), 3.45 (s, 3 H, N₁-CH₃), 3.8 (s, 3H, OCH₃), 4.0 (s, 3 H, N₇-CH₃), 7.0 (d, 1 H, J = 8 Hz), 7.2 (d, 1 H, J = 16 Hz), 7.66 (d, 1 H, J = 16 Hz), 7.72 (d, 1 H, J = 8 Hz). MS (CI/NH₃): m/e 327 (MH⁺, base) 205.

1,3-Dimethyl-8-[4-(dimethylamino)styryl]xanthine (30a). A solution of 4-(dimethylamino)cinnamic acid (0.1 g, 0.52 mmol), 1-hydroxybenzotriazole (0.14 g, 1.04 mmol), and EDAC (0.19 g, 1.04 mmol) in DMF (1 mL) was sonicated for 1 h. 1,3-Dimethyl-

5,6-diaminouracil (0.088 g, 0.52 mmol) was added, and the mixture was heated for 3 h at 80 °C. The dark red solution was cooled to room temperature, and the product was obtained as a deep yellow precipitate (0.045 g). An additional crop was obtained by cooling the mother liquor in an ice bath and adding 10 volumes of brine (combined yield 38%). ¹H NMR CD₃OD: δ 7.54 (d, 1 H, J = 15.5 Hz), 7.45 (d, 2 H, 8.8 Hz), 6.74 (d, 2 H, J = 8.8 Hz), 6.56 (d, 1 H, J = 15.5 Hz), 3.42, 3.27 (s, 3 H, CH₃), 3.00 (s, 6 H, N(CH₃)₂). MS (CI): m/e 344 (MH⁺).

The above amide (0.045 g, 0.13 mmol) was suspended in methanol (1 mL), and 4 N NaOH (1 mL) was added. The resulting solution was stirred at 80–90 °C for 1.5 h. HCl (18%) was added carefully to the ice-cooled reaction solution to pH = 7–8. A yellow precipitate was obtained (0.018 g, 43%). ¹H NMR DMSO- d_6 : δ 7.54 (d, 1 H, J = 16 Hz), 7.44 (d, 2 H, J = 8.5 Hz), 6.74 (d, 2 H, J = 16 Hz), 3.47, 3.25 (s, 3 H, CH₃), 2.97 (s, 6 H, N(CH₃)₂). MS (CI): m/e 326 (MH⁺).

1,3-Dimethyl-8-(2,3-dimethoxystyryl)xanthine (31a). Compound 31a was made from 2,3-dimethoxycinnamic acid according to general procedure A (recrystallized from methanol). Mp: 299–301 °C. ¹H NMR DMSO- d_6 : δ 3.25 (s, 3 H, N₃-CH₃), 3.47 (s, 3 H, NCH₃), 3.78 (s, 3 H, OCH₃), 3.82 (s, 3 H, OCH₃), 7.05 (d, 1 H, J = 17 Hz), 7.05 (dd, 1 H, J = 2, 8 Hz), 7.11 (t, 1 H, J = 8 Hz) 7.26 (dd, 1 H, J = 2, 8 Hz), 7.84 (d, 1 H, J = 17 Hz) MS (CI/NH₃): m/e 360 (M + NH₄+), 343 (base peak).

1,3,7-Trimethyl-8-(2,3-dimethoxystyryl)xanthine (31b). Compound 31b was made from 31a according to the general procedure B. Mp: 233-235 °C. ¹H NMR DMSO- d_6 : δ 323 (s, 3 H, NCH₃), 3.47 (s, 3 H, NCH₃), 3.78 (s, 3 H, OCH₃), 3.83 (s, 3 H, OCH₃), 4.02 (s, 3 H, N₇-CH₃), 7.06 (d, 1 H, J = 8 Hz), 7.10 (t, 1 H, J = 8 Hz), 7.32 (d, 1 H, J = 16 Hz), 7.51 (d, 1 H, J = 8 Hz), 7.90 (d, 1 H, J = 16 Hz). MS (EI): m/e 356 (base), 325.

1,3-Dimethyl-8-(3,4-dimethoxystyryl)xanthine (32a). Compound 32a was made from 3,4-dimethoxycinnamic acid according to general procedure A. Mp: >320 °C. ¹H NMR DMSO- d_6 : δ 3.25 (s, 3 H, N₃-CH₃), 3.46 (s, 3 H, N₁-CH₃), 3.78 (s, 3 H, OCH₃), 3.82 (s, 3 H, OCH₃), 6.96 (d, 1 H, J = 16 Hz), 6.98 (d, 1 H, J = 8 Hz), 7.14 (d, 1 H, J = 8 Hz), 7.25 (s, 1 H). MS (CI/NH₃): m/e 343 (MH⁺), 172 (base peak).

1,3,7-Trimethyl-8-(3,4-dimethoxystyryl)xanthine (32b). Compound 32b was made from 32a according to general procedure B. Mp: 230–232 °C. ¹H NMR DMSO- d_6 : δ 3.29 (s, 3 H, N₃-CH₃), 3.52 (s, 3 H, N₇-CH₃), 3.85 (s, 3 H, OCH₃), 3.9 (s, 3 H, OCH₃), 4.09 (s, 3 H, N₇-CH₃), 7.05 (d, 1 H, J = 8 Hz), 7.25 (d, 1 H, J = 16 Hz), 7.30 (d, 1 H, J = 8 Hz), 7.48 (s, 1 H), 7.66 (d, 1 H, J = 16 Hz). MS (CI): m/e 357 (MH⁺ base), 209.

1,3-Dimethyl-8-(3,5-dimethoxystyryl)xanthine (33a). Compound 33a was made from 3,5-dimethoxycinnamic acid according to general procedure A. Mp: >320 °C. ¹H NMR DMSO- d_6 : δ 3.24 (s, 3 H, N₃-CH₃), 3.46 (s, 3 H, N₁-CH₃), 3.78 (s, 6 H, OCH₃), 6.5 (s, 1 H), 6.78 (s, 2 H), 7.02 (d, 1 H, J = 16 Hz), 7.54 (d, 1 H, J = 16 Hz). MS (CI): m/e 343 (MH⁺ base), 166, 136.

1,3,7-Trimethyl-8-(3,5-dimethoxystyryl)xanthine (33b). Compound 33b was made from 33a according to general procedure B. Mp: 228–230 °C. ¹H NMR DMSO- d_6 : δ 3.22 (s, 3 H, N₃-CH₃), 3.45 (s, 3 H, N₁-CH₃), 3.79 (s, 6 H, OCH₃), 4.04 (s, 3 H, N₇-CH₃), 6.5 (s, 1 H), 6.97 (s, 2 H), 7.32 (d, 1 H, J = 16 Hz), 7.58 (d, 1 H, J = 16 Hz).

General Procedure C: Demethylation Followed by O-Alkylation of 8-(3,5-Dimethoxy-4-hydroxystyryl)xanthines. 1,3,7-Trialkyl-8-(3,4,5-trimethoxystyryl)xanthine (1 equiv) was dissolved in a minimum of DMF, and 1.5 equiv of sodium thiophenoxide was added. The solution was heated to 150-160 °C for 20 min or until judged complete using TLC. Ether was added, and the resulting orange precipitate was isolated by filtration. This solid was dissolved in DMF, and water and 6 N HCl were added until pH 2 to give 35 as a yellow precipitate. The appropriate halide (2 equiv for monohalide and 8 equiv for dihalide) was added to a solution of 35 in DMF, followed by finely powdered, anhydrous K₂CO₃. The solution was left in an ultrasonic bath for 15 min and further heated at 50-80 °C for 2 h or until judged complete using TLC. The reaction mixture was cooled and extracted with petroleum ether. The crude product was precipitated by water (for product of reaction with monohalides) or reacted further (for dihalides) with concentrated aqueous ammonia and chromatographed on preparative TLC

using 90-95% chloroform/5-10% methanol/1% aqueous ammonia. This procedure was used to make compounds 37-40.

The 4-hydroxy intermediate 35 was also recrystallized (MeOH/ H_2O). ¹H NMR DMSO- d_6 : δ 3.23 and 3.46 (each s, 3 H, N_1 - and N_3 -CH₃); 3.83 (s, 6 H, 3,5-(OCH₃)), 4.03 (s, 3 H, N_7 -CH₃), 7.08 (s, 2 H, Ar), 7.18 and 7.61 (each d, 1 H, C=C, J = 15.7 Hz), 8.82 (br s, 1 H, ArOH).

1,3,7-Trimethyl-8-[3,5-dimethoxy-4-(benzyloxy)styryl]xanthine (37). Compound 37 was made from benzyl bromide according to general procedure C. Mp: 190-195 °C. ¹H NMR CDCl₃: δ 3.42 (s, 3 H, N₃CH₃), 3.63 (s, 3 H N₅CH₃), 3.89 (s, 6 H, OCH_3), 5.06 (s, 2 H, OCH_2), 6.8 (s, 2 H), 6.78 (d, 1 H, J = 16 Hz), $7.3-7.5 \text{ (m, 5 H)}, 7.7 \text{ (d, 1 H, } J = 16 \text{ Hz)}. \text{ MS (CI)}: m/e 463 \text{ (MH}^+$ base), 375, 357.

1,3,7-Trimethyl-8-[3,5-dimethoxy-4-[(4-aminobutyl)oxy]styryl]xanthine (38). Compound 38 was made from 1,4dibromobutane according to general procedure C. MS (Cl): m/e444 (MH+ base), 373, 359.

1,3,7-Trimethyl-8-[3,5-dimethoxy-4-[[4-[(tert-butyloxy)carbonyl]amino]butyl]oxy]styryl]xanthine (39). Compound 39 was made from 38 using di-tert-butyl dicarbonate in CHCl₃ (30 min). The chloroform was removed under a stream of N2, and the crude product was purified using a preparative plate (silica, ethyl acetate/petroleum ether, 70:30). ¹H NMR CDCl₃: δ 1.41 (s, 9 H, CH₃), 1.6–1.8 (m, 4 H, CH₂), 3.2 (m, 2 H, CH_2NH), 4.0 (m, 2 H, OCH_2), 3.39 (s, 3 H, N_3 - CH_3), 3.6 (s, 2 H, N₇-CH₃), 3.88 (s, 6 H, OCH₃), 4.05 (s, 3 H, N₇-CH₃), 6.74 (s, 2 H), 6.75 (d, 1 H, J = 16 Hz), 7.7 (d, 1 H, J = 16 Hz). MS (CI): m/e544 (MH+ base) 44, 359.

1,3,7-Trimethyl-8-[3,5-dimethoxy-4-[(4-amino-trans-butenyl)oxy]styryl]xanthine (40). Compound 40 was made from 1.4-dibromo-trans-2-butene according to general procedure C. ¹H NMR CDCl₃: δ 3.41 (s, 3 H, N₃-CH₃), 3.63 (s, 3 H, N₁-CH₃), 3.91 (s, 6 H, OCH₃), 4.06 (s, 3 H, N₇-CH₃), 4.43 (s, 2 H, CH₂NH₂), 5.94 (s, 2 H, OCH₆), 6.78 (s, 2 H), 6.79 (d, 1 H, J = 16 Hz). MS (CI): m/e 442 (MH+ base) 373, 357, 124.

7-Ethyl-1,3-trimethyl-8-(3,4,5-trimethoxystyryl)xanthine (44c). Compound 44c was made from compound 44a according to general procedure B, except that ethyl iodide was used instead of methyl iodide. ¹H NMR DMSO- d_6 : δ 1.34 (t, 3) H, CH_3Et , J = 7 Hz), 3.25 and 3.47 (each s, 3 H, NCH_3), 3.70 (s, 4 H, 4-OCH₃), 3.86 (s, 6 H, 3,5=(OCH₃)), 4.54 (q, 2 H, N₇-CH₂), 7.13 (s, 2 H, Ar), 7.30 and 7.68 (each d, 1 H, C=C, J = 16 Hz).

1,3-Dipropyl-7-methyl-8-styrylxanthine (47). 5-Amino-6nitroso-1,3-dipropyluracil^{10,20} was suspended in DMF (10 mmol/ 100 mL) and hydrogenated over 5% Pd/C at 40 psi overnight. The clear solution was filtered through Celite and could be stored at -20 °C.

trans-Cinnamic acid (0.47 g) and EDAC (0.65 g) were added to 2.1 mmol of the above solution and stirred for 4h. An additional 0.3 g of EDAC was added. After an additional 2 h, half-saturated NaCl solution was added and the mixture was extracted with ethyl acetate (6×). The organic layer was dried over Na₂SO₄ and evaporated to an oil, which was used without further purification.

The above oil was dissolved in methanol (30 mL) and treated with 4 N NaOH (20 mL). After refluxing for 15 min, the mixture was cooled, ice was added, and it was acidified using 6 N HCl. A precipitate formed and was recovered by filtration. The NMR and MS were consistent with the assigned structure of 47. Recrystallized from DMF/water.

 ϵ_{342} for 47 in methanol (λ_{max}) was 35 100. A smaller absorption peak was at 265 nm.

1,3,7-Trimethyl-8-[2-(3-aminophenyl)ethyl]xanthine (57). Compound 54 was made from 21b with H₂/Pd at 50 psi in DMF for 3 h. Mp: 158-160 °C. ¹H NMR DMSO-d₆: δ 2.82 (t, 2 H, J = 8 Hz), 2.96 (t, 2 H, J = 8 Hz), 3.20 (s, 3 H, NCH₃), 3.42 (s, 3 H, NCH₃), 3.69 (s, 3 H, N₇-CH₃), 4.95 (s, 2 H, NH₂), 6.34-6.39 $(3 \text{ H}, \text{H-2}, \text{H-4}, \text{H-6}), 6.90 \text{ (t, 1 H}, J = 8 \text{ Hz}, \text{H-5}). \text{ MS } (\text{CI/NH}_3):$ m/e 314 (MH+).

Biological Methods. Receptor Binding. Rat cerebral cortical membranes and striatal membranes were prepared 12,13 and treated with adenosine deaminase (2 units/mL) for 30 min at 37 °C prior to storage at -70 °C. Solid samples of the adenosine derivatives were dissolved in DMSO and stored in the dark at -20 °C. The stock solutions were diluted with DMSO to a concentration of ≤0.1 mM prior to adding to the aqueous medium.

The final concentration of DMSO in the assay medium was generally 2%.

Inhibition of binding of 1 nM [3H]-N6-(2-phenylisopropyl)adenosine (Du Pont NEN, Boston, MA) to A1-receptors in rat cerebral cortex membranes was measured as described. 17 Membranes ($\sim 100 \,\mu g$ of protein/tube) were incubated for 1.5 h at 37 °C in a total volume of 0.5 mL of 50 mM Tris HCl, at pH 7.4. Test drugs were dissolved in DMSO and added in 10-µL aliquots, resulting in a final DMSO concentration of 2%. Bound and free radioligand were separated by addition of 3 mL of a buffer containing 50 mM Tris HCl at pH 7.4 at 5 °C followed by vacuum filtration using a Brandel cell harvester (Brandel, Gaithersburg, MD) and a Whatman GF/B glass-fiber filter with additional washes totaling 9 mL of buffer. Nonspecific binding was determined with 10 μ M 2-chloroadenosine.

Inhibition of binding of 5 nM [3H]CGS 21680 was carried out as follows. Membranes ($\sim 80 \mu g$ of protein/tube, prepared according to ref 8) were incubated for 1 h at 25 °C in a total volume of 0.5 mL of 50 mM Tris HCl containing 10 mM MgCl₂ at pH 7.4. Test drugs were dissolved in DMSO and added in 10-μL aliquots, resulting in a final DMSO concentration of 2%. Nonspecific binding was defined using 20 μ M 2-chloroadenosine. Filtration was carried out using a Brandel cell harvester, as above, using Tris HCl/MgCl₂ as the washing buffer.

At least six different concentrations spanning 3 orders of magnitude, adjusted appropriately for the IC_{50} of each compound, were used. IC₅₀ values, computer-generated using a nonlinear regression formula on the GraphPAD program (Institute for Scientific Information), were converted to apparent K_i values using K_D values^{12,13} of 1.0 and 14 nM for [3H]PIA and [3H]CGS 21680 binding, respectively, and the Cheng-Prusoff equation.¹⁸
