(Received November 30th, 1970)

SUMMARY

Refined values of the CO stretching force constants for monosubstituted metal pentacarbonyl complexes have been obtained by rigorous direct methods of calculation.

The following compounds have been treated by this method: manganese carbonyl complexes, halogenometal pentacarbonyls, some recently prepared aminocarbene complexes $[RHN(Me)C]Cr(CO)_5$, carbene pentacarbonyl compounds $[R(OC_2H_5)C]M(CO)_5$ ($R = CH_3, n-C_4H_9$ and $M = Cr, W$), phosphacarborane metal carbonyls of general formula $(CH_3)_4N[B_9H_{10}CHE \cdot M(CO)_5]$ with $E = P, As$ and $M = Mo, W, Cr$ and arsine pentacarbonyl complexes of Cr, Mo and W.

Using the more exact carbonyl stretching force constants obtainable from such calculations, relative σ and π Graham parameters for a series of $LM_n(CO)_5$ compounds have been derived. The relative importance of σ and π bonding in some organotin derivatives is discussed.

CALCULATION OF FORCE CONSTANTS

Using the Cotton and Kraihanzel force field¹ and the orbital overlap theories outlined by Jones², a more exact method for the direct calculation of CO stretching force constants of complexes of the general formula $LM(CO)_5$ has recently been presented³.

Previously, all papers dealing with calculations of force constants in the CO stretching region for substituted metal carbonyls used the Cotton and Kraihanzel approximative method which enabled only three of the five related force constants to be evaluated, and in an attempt to resolve this problem. Dalton *et al.*⁴ have published some interesting interaction force constant relationships by introducing angular correction terms in the treatment of Jones². As mentioned earlier this procedure does not improve the results.

If however, the interaction force constants relations and the rigorous algebraic

(continued on p. 394)

method described in Part III of this series are used, all the CO stretching force constants of monosubstituted metal carbonyls $\text{LM}(\text{CO})_5$ may be calculated with great precision. This method has now been applied to a second series of $\text{LM}(\text{CO})_5$ compounds and the results are presented in Table 1.

The calculations were mainly carried out in double precision on an IBM 360 type 30 computer of the Digital Computing Laboratory of the University of Ghent.

SEPARATION OF INDUCTIVE AND MESOMERIC EFFECTS

CO stretching frequencies and force constant shifts in substituted metal carbonyls are currently interpreted in terms of the differences in π bonding ability between the ligands¹⁴, although in some infrared studies¹⁵ it has been suggested that is the σ bonding ability of the ligand and not its π bonding capacity which is the principal factor in determining the CO stretching frequencies of the complex.

In a particularly interesting paper¹⁶, Graham has assumed that inductive effects operating through the ligand-metal σ bond, and ligand-metal π bonding, are both important in determining the carbonyl stretching force constants in complexes of the type $\text{LM}(\text{CO})_5$ ($\text{M} = \text{Mo}, \text{Mn}$).

In order to separate the inductive and mesomeric effects, the following simple relations have been suggested by Graham:

$$\Delta k_1 = k'_1 - k_1 = m \cdot \Delta\sigma + n \cdot \Delta\pi$$

$$\Delta k_2 = k'_2 - k_2 = \Delta\sigma + \Delta\pi$$

with $m=1$ and $n=2$. In these equations k'_1 and k_1 are the stretching force constants of the carbonyl group *trans* to L in the compound considered and in the reference compound respectively, while k'_2 and k_2 are the related stretching force constants of the carbonyl groups *cis* to L. $\Delta\sigma$ and $\Delta\pi$ are the differences between the σ inductive and π acceptor properties of the ligands. The coefficient $m=1$ is introduced to allow for the assumption that the inductive effect of the ligand operates equally over all five CO groups, whereas the coefficient $n=2$ simply arises from the splitting of the over-all change in the π portion according to the treatment of Jones².

Using these equations the σ and π parameters for a series of pentacarbonyl-manganese derivatives $\text{LMn}(\text{CO})_5$ have been calculated, some of them for the first time. As the required experimental stretching force constants k_1 and k_2 are closely related to the interaction force constants, and since the calculation method³ used here allows the direct evaluation of all five of the most important CO force constants, all in perfect agreement with the vibrational data, the parameters presented in Table 2 are considered more accurate.

Despite the increased accuracy, however the magnitude acid variation of σ and π donor-acceptor properties is very similar to that found by Graham¹⁶. However, $\text{HMn}(\text{CO})_5$ is preferred as the reference compound over $\text{CH}_3\text{Mn}(\text{CO})_5$ as force constant values for the former have been calculated exactly using the isotopic substitution method¹⁷.

It is pertinent to query the justification for the calculation of force constants to nine significant figures, despite the fact that from such calculations it is possible to

^a All spectra were measured in cyclohexane solution. Force constants have been taken from parts III and VII of this series. ^b Reference.

reproduce the experimental values for the wave numbers perfectly to within 1×10^{-10} cm^{-1} .

The experimental precision in determining the force constants is, of course, not nearly so high. Indeed, on the assumption that they are mutually independent, root mean square errors m (standard deviations σ) of ± 1 cm^{-1} in each of the four bands in a typical case of $LM(CO)_5$ compounds, change the values of k_1 and k_2 by m equal to 0.029 and 0.013 mdyne/Å, and of k_c , k_e , and k_t by m equal to 0.010, 0.011 and 0.0065 mdyne/Å respectively. Actually such an experimental precision is an upper limit, since it pre-supposes the comparison of spectra obtained under the most favorable conditions and in one and the same solvent. The corresponding uncertainties for the σ and π parameters are easy to evaluate.

The progression of σ and π parameters in some tin derivatives, as reported in Table 3, is one interesting aspect of the results. A comparison of the parameters found by Graham¹⁶ on the basis of the Cotton and Kraihanzel approximate force constant calculation method (needing only three frequencies) with those derived from the rigorous algebraic approach presented here (using all four frequencies) suggests that

TABLE 3

INFLUENCE OF FORCE CONSTANTS CALCULATION METHODS ON σ AND π PARAMETERS FOR $(R_{3-n}SnX_n)Mn(CO)_5$

$R_{3-n}SnX_n$	σ_1^a	σ_2^b	π_1^a	π_2^b
$(CH_3)_3Sn$	-0.612	-0.84	0.230	0.51
$(CH_3)_2SnCl$	-0.497 ^c	-0.66	0.344	0.56
	-0.122 ^d		0.034 ^d	
CH_3SnCl_2	^f	0.02	^f	0.23
$SnCl_3$	0.383 ^{e-f}	0.18	-0.010 ^{e-f}	0.31
$(C_6H_5)_3Sn$	-0.328	-0.59	0.091	0.41
$(C_6H_5)_2SnCl$	-0.121	-0.38	0.140	0.43
$C_6H_5SnCl_2$	0.187	-0.04	0.018	0.29
$SnCl_3$	0.383 ^{e-f}	0.18	-0.010 ^{e-f}	0.31
$(C_6H_5)_3Sn$	-0.328	-0.59	0.091	0.41
$(C_6H_5)_2SnC_6F_5$	-0.270	-0.52	0.187	0.49
$C_6H_5Sn(C_6F_5)_2$	-0.082	-0.31	0.129	0.41
$Sn(C_6F_5)_3$	0.199	-0.27	0.052	0.51

^a σ_1 , π_1 : σ and π parameters obtained in this study. ^b σ_2 , π_2 : Graham σ and π parameters. ^c Ref. 5. ^d Ref. 4. ^e $SnBr_3$. ^f Force constants calculations for these compounds could not be made as the B_1 mode of these derivatives has not, as yet, been assigned.

the significance of differences in force constants in series of related compounds is not so absolute as generally stated. It appears that particular trends in the π parameter may be reversed by applying another, more exact, method of calculation.

The increasing trend in the σ parameter with progressive chlorine or C_6H_5 substitution is as expected. The overall effect of this progressive substitution means that the substituted tin group becomes a weaker σ donor ligand with every new substitution. As a result of this effect the contraction of the filled d orbitals of manganese will progressively increase, reducing their overlap with the antibonding π orbital on carbon monoxide and hence increasing the CO stretching frequency. At the same time, the excess negative charge built up on manganese by donor σ bonding, and available for back donation to the ligand, should decrease.

The changes and fluctuations in the π parameter are not so clear-cut. With the introduction of the first electronegative substituent (chlorine or C_6F_5 group) in the R_3Sn ligand, the π parameter appears to rise, suggesting that there should be an increase in π electron withdrawal from manganese to tin. This result, however, does not fit the expected synergic character in the metal-ligand bond, although the change in the π parameter also results in an increase of $\nu(CO)$.

Tin itself has d_π orbitals which could be sensitive to electronegative substituents, and for this reason, the first chlorine or C_6F_5 substituent could cause a contraction of these tin d_π orbitals, increasing their π bonding with the manganese atom. This could be a possible explanation for the observed increase of the π parameter.

The second substitution, however, gives rise to a drop of the parameter for π acceptor ability, in agreement with the synergic interaction, while the third substitution leads to an increase of the Graham π parameter, when the approximate evaluation method is used, but yields a further decrease of the π parameter if the rigorous direct

calculation method is applied. The latter effect is more logical than the former, for if this result is accepted, decreases of the π parameter after a second and third substitution could be interpreted as a result of the contribution of two simultaneous processes, (a) a further contraction of the tin d_{π} orbitals beyond the ideal extent for overlap with the manganese d orbitals, and (b) a back donation from the electronegative substituent to tin¹⁹, which also would reduce the π acceptor capacity of tin with respect to the manganese atom. Such a suggestion agrees with a partial decrease of $\nu(\text{CO})$, which is evidently cancelled by a greater potential increase of $\nu(\text{CO})$ due to the inductive effect.

In general, these results point out the relative importance of the σ donor effect at the expense of the mesomeric effect.

Finally, it should be stated that, as suggested by Gay and Graham²⁰, it will be necessary to examine the IR spectra of isotopic enriched species in order to arrive at less speculative interpretations regarding the relation of CO stretching force constants to chemical bonding. However, this refinement does not eliminate the need to integrate both $\nu(\text{M}-\text{C})$ and $\nu(\text{M}-\text{L})$ in the carbonyl stretching force constants calculations.

ACKNOWLEDGEMENT

The authors wish to thank Prof. Dr. C. C. Grosjean for permission to use the computing facilities of his institute and Miss. Lic. R. M. De Caluwe and Dr. H. Steyaert for executing the computer programs. They also wish to express their gratitude to Dr. E. V. Van den Berghe for many helpful discussions.
