

## NOTE

# SPECTRA, STRUCTURES, AND BONDING OF SOME URANIUM(IV) CYCLOPENTADIENYLS

MELVIN L. ANDERSON AND LARRY R. CRISLER

*Dow Chemical Company, Rocky Flats Division, Golden, Colorado 80401 (U.S.A.)*

(Received November 25th, 1968; in revised form February 13th, 1969)

We report in this paper some data on tetracyclopentadienyluranium,  $\text{UCp}_4$ , tricyclopentadienyluranium chloride,  $\text{UCp}_3\text{Cl}$ , and tricyclopentadienyluranium tetrahydroborate,  $\text{UCp}_3\text{BH}_4$  ( $\text{Cp}=\text{C}_5\text{H}_5$ ). Some mention will also be made of the tricyclopentadienyluranium ion,  $\text{UCp}_3^+$ . Both  $\text{UCp}_3\text{Cl}$  and  $\text{UCp}_4$  have been previously reported<sup>1,2</sup> and our data supplement the literature. The preparation and properties of  $\text{UCp}_3\text{BH}_4$ , reported only in a dissertation<sup>3</sup>, are described and discussed.

## EXPERIMENTAL

### Syntheses

Preparative reactions were performed in a dry nitrogen atmosphere. Tetrahydrofuran was distilled from  $\text{LiAlH}_4$  and purged with dry  $\text{N}_2$  before use; benzene was treated successively with  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{O}$ ,  $\text{NaOH}$ , and  $\text{H}_2\text{O}$ , distilled from  $\text{P}_4\text{O}_{10}$ , and purged with dry  $\text{N}_2$ .

Uranium tetrachloride, from which all other compounds were synthesized, directly or indirectly, was prepared by the procedure of Hermann and Suttle<sup>4</sup> in which the orange modification of uranium trioxide was treated with hexachloropropene. Orange  $\text{UO}_3$ , in turn, had been prepared by a method essentially similar to that used by Selbin *et al.*<sup>5</sup>

Tricyclopentadienyluranium chloride was prepared by stirring  $\text{UCl}_4$  with the theoretical amount of  $\text{TiCp}$  (Alfa Inorganics, Inc.) for 1–2 h either in THF at room temperature or in benzene under reflux. The product mixture was filtered to remove insoluble  $\text{TiCl}$ , solvent removed *in vacuo*, and dark brown  $\text{UCp}_3\text{Cl}$  isolated (90% yield) from the residue by sublimation at  $210^\circ$  and *ca.*  $10^{-4}$  mm.

Tetracyclopentadienyluranium was synthesized in *ca.* 20% yield by treatment of  $\text{UCl}_4$  in refluxing THF with a 2.5-fold excess of  $\text{NaCp}$ . This was followed by careful removal of the solvent under vacuum and sublimation at  $195^\circ$  and  $10^{-4}$  mm of the bright red  $\text{UCp}_4$ .

A typical synthesis of  $\text{UCp}_3\text{BH}_4$  was as follows: To a freshly prepared solution containing 1.3 mmoles of  $\text{UCp}_3\text{Cl}$  in 125 ml of THF was added 0.114 g (3.0 mmoles) of  $\text{NaBH}_4$ . Stirring of the reaction mixture at room temperature for 16 h followed.

The NaCl and excess NaBH<sub>4</sub> were removed by filtration through fine sintered glass; solvent was removed from the filtrate *in vacuo* at room temperature. The resultant brown solid then was sublimed at 170° and 10<sup>-4</sup> mm to produce red-orange, crystalline UCp<sub>3</sub>BH<sub>4</sub> in 95% yield. Identification of the product as UCp<sub>3</sub>BH<sub>4</sub> was done by mass spectrometry.

### Spectra

Visible and near-infrared spectra from 400 to 2600 nm for UCp<sub>3</sub>Cl and UCp<sub>3</sub>-BH<sub>4</sub> and from 400 to 1400 nm for UCp<sub>4</sub> and UCp<sub>3</sub><sup>+</sup> (UCp<sub>3</sub>Cl in deoxygenated H<sub>2</sub>O) were obtained on a Cary Model 14 spectrophotometer with stoppered 1-cm silica cells. Infrared spectra of UCp<sub>3</sub>Cl, UCp<sub>4</sub>, and UCp<sub>3</sub>BH<sub>4</sub> were obtained on KBr pellets in the range of 4000–250 cm<sup>-1</sup> using a Perkin-Elmer Model 521 spectrometer.

Mass spectral measurements were recorded using a C.E.C. Model 21-110B double-focusing spectrometer equipped with a direct probe inlet. Typical conditions for UCp<sub>3</sub>Cl, *e.g.* were probe temperature 120°, block temperature 170°, and pressure 1 × 10<sup>-6</sup> mm.

## RESULTS AND DISCUSSION

### Electronic spectra

The visible spectra of UCp<sub>3</sub>Cl and UCp<sub>3</sub><sup>+</sup> from 400–800 nm have been presented by Reynolds and Wilkinson<sup>1</sup>. Our spectra of these species agree with the reported spectra, except from about 750–800 nm where it appears that the detector of the instrument used by the former workers may have been insensitive.

Molar extinction coefficients for UCp<sub>3</sub>BH<sub>4</sub> are about a factor of two larger than values in the same wavelength regions for UCp<sub>3</sub>Cl<sup>1</sup>, *viz.* in 7.0 × 10<sup>-4</sup> M UCp<sub>3</sub>-BH<sub>4</sub>, ε = 390 at 533 nm and 200 at 747 nm. No extinction coefficients were determined for UCp<sub>4</sub> due to rapid decomposition of the compound on manipulation of its solutions.

Except for the strong shoulder peaks at 425 and 510 nm, the absorption bands for UCp<sub>4</sub> appear weak relative to those for the other uranium cyclopentadienyl compounds; this may be due to the symmetrical tetrahedral structure<sup>2</sup> of the former. Thus, using arguments analogous to those of Gans *et al.*<sup>6</sup>, it is suggested that the tetrahedral symmetry of UCp<sub>4</sub> is destroyed by substituting for one Cp ligand such non-equivalent ligands as H<sub>2</sub>O, BH<sub>4</sub>, or Cl. Although exact structures of UCp<sub>3</sub>BH<sub>4</sub> (in C<sub>6</sub>H<sub>6</sub>) and the aquated UCp<sub>3</sub>(H<sub>2</sub>O)<sub>x</sub><sup>+</sup> species are unknown, a single crystal study of UCp<sub>3</sub>Cl has shown it to be a distorted tetrahedron with a monoclinic crystal structure<sup>7</sup>. It is of interest here that X-ray powder pattern data indicate that none of the compounds, UCp<sub>4</sub>, UCp<sub>3</sub>BH<sub>4</sub>, or UCp<sub>3</sub>Cl, as well as the n-butoxide, UCp<sub>3</sub>-OC<sub>4</sub>H<sub>9</sub>, reported by Ter Haar and Dubeck<sup>8</sup>, are isomorphous.

Term assignments of all major peaks in the visible near-infrared spectra of our uranium cyclopentadienyl compounds have been made and are given in Table 1. The assignments are based mainly on the various spectra of U<sup>IV</sup> compounds reported by Gans *et al.*<sup>6</sup> and can be interpreted in terms of 5f<sup>2</sup> electronic configurations for the uranium atom in the cyclopentadienyls. Some of the absorption bands in the table, especially those assigned to the <sup>3</sup>P<sub>0</sub> and <sup>3</sup>F<sub>3</sub> terms, are generally somewhat lower in frequency than values reported for other U<sup>IV</sup> species<sup>6</sup>.

TABLE I. ELECTRONIC SPECTRAL WAVENUMBERS AND TERM ASSIGNMENTS

### Mass spectra

The mass spectrum of UCp<sub>4</sub> at 70 eV appears normal in that the first Cp ligand is readily removed but the remaining ligands are increasingly difficult to strip off. In the case of UCp<sub>3</sub>Cl, the ionic<sup>1,3,7</sup> U-Cl bond is more difficult to rupture than the more covalent U-C bond(s). However, a parallel in the mass spectra of UCp<sub>4</sub> and UCp<sub>3</sub>Cl is evident in the nearly constant relative intensity values found for the UCp<sub>x</sub><sup>+</sup> ions for UCp<sub>4</sub> and the corresponding UCp<sub>x-1</sub>Cl<sup>+</sup> ions (where x = 3, 2, or 1, respectively) from UCp<sub>3</sub>Cl. Thus, mass spectra are insensitive to the proposed<sup>3</sup> trend in U-Cp bond character from the more ionic UCp<sub>4</sub> to the more covalent UCp<sub>3</sub>Cl.

The fragmentation pattern of the tetrahydroborate appears somewhat unusual with the most intense peak that for the UCp<sub>2</sub><sup>+</sup> ion, *i.e.* an ion resulting from the loss of two substituents rather than one. That this is not caused by the high ionizing voltage was shown in that even at 15 eV the UCp<sub>2</sub><sup>+</sup> ion was the most prominent and all other fragment ions were relatively weak in intensity. Thus, under the conditions of the mass spectrometer, the U-C bond(s) in UCp<sub>3</sub>BH<sub>4</sub> are generally stronger than the U-BH<sub>4</sub> bond. Our results on UCp<sub>3</sub>BH<sub>4</sub> are similar in some respects to the mass spectral cracking pattern of the compound ZrCp<sub>2</sub>(H)BH<sub>4</sub><sup>9</sup> from which it was suggested that the ion ZrCp<sub>2</sub><sup>+</sup> is particularly stable. In addition, these authors report a weak parent ion in the mass spectrum of ZrCp<sub>2</sub>(BH<sub>4</sub>)<sub>2</sub>.

### Infrared spectra

Our infrared spectra of UCp<sub>3</sub>Cl, UCp<sub>4</sub>, and UCp<sub>3</sub>BH<sub>4</sub> from 4000-667 cm<sup>-1</sup>

agree reasonably well with the literature<sup>1-3</sup>. In the far infrared region the following absorption bands ( $\text{cm}^{-1}$ ) and relative intensities were found:  $\text{UCp}_3\text{Cl}$ , 594 w and 298 vw;  $\text{UCp}_4$ , 609 s and 593 s;  $\text{UCp}_3\text{BH}_4$ , 415 w, 332 m, and 260 m. The bands in the  $300\text{ cm}^{-1}$  region are likely due to metal-Cp ring stretching while those near  $600\text{ cm}^{-1}$  may arise from out-of-plane ring deformations<sup>10</sup>. Additional possible significance of the strong doublet at 609 and  $593\text{ cm}^{-1}$  for  $\text{UCp}_4$  must await reports of similar spectra for other metal cyclopentadienyls.

In the C-H-stretching region,  $\text{UCp}_3\text{Cl}$  gives rise to only the asymmetric band at  $3068\text{ cm}^{-1}$ , while  $\text{UCp}_3\text{BH}_4$  and  $\text{UCp}_4$  each show, in addition, a symmetric stretching band near  $2925\text{ cm}^{-1}$ . Although Hristidu reported<sup>3</sup> a band at  $2924\text{ cm}^{-1}$  for  $\text{UCp}_3\text{Cl}$ , we found, in agreement with earlier workers<sup>1</sup>, that such a band can arise from decomposition. The absence of a symmetric C-H-stretching band may thus indicate predominantly  $\pi$ -U-Cp bonding in  $\text{UCp}_3\text{Cl}$ <sup>11</sup>. The metal-Cp ring bands in  $\text{UCp}_4$  and  $\text{UCp}_3\text{BH}_4$  may, therefore, possess some degree of  $\sigma$  character. This is in general agreement with Hristidu<sup>3</sup>, who claimed a decreasing degree of ionic character in the series  $\text{UCp}_4$ ,  $\text{UCp}_3$ ,  $\text{UCp}_3\text{BH}_4$ ,  $\text{UCp}_3\text{Cl}$ , and  $\text{UCp}_3\text{OC}_2\text{H}_5$ .

Band positions of the  $\text{BH}_4$  ligand in  $\text{UCp}_3\text{BH}_4$  compare closely with those reported for  $\text{ZrCp}_2(\text{BH}_4)_2$ <sup>12</sup> but differ significantly from the spectrum of  $\text{TiCp}_2\text{-BH}_4$ <sup>13</sup>, e.g. the asymmetric B-H bridge stretching frequency is estimated from the spectrum of the titanium compound to be  $2041\text{ cm}^{-1}$ , or over 100 wavenumbers lower than the corresponding frequencies for  $\text{UCp}_3\text{BH}_4$  ( $2142\text{ cm}^{-1}$ ) and  $\text{ZrCp}_2\text{-}(\text{BH}_4)_2$  ( $2149\text{ cm}^{-1}$ ). Additionally, a strong Ti-H stretching band is reported at  $1942\text{ cm}^{-1}$  but analogous metal-hydrogen bands are absent in the spectra of the uranium and zirconium compounds. Therefore,  $\text{UCp}_3\text{BH}_4$  is probably nearer to the double-hydrogen bridged structure proposed<sup>14</sup> for  $\text{ZrCp}_2(\text{BH}_4)_2$  as opposed to the Ti-H bond and coordinated  $\text{BH}_3$  group suggested<sup>13</sup>, but not proven unequivocally, for  $\text{TiCp}_2\text{BH}_4$ .

#### ACKNOWLEDGEMENT

This work was supported by the U.S. Atomic Energy Commission under Contract AT(29-1)-1106.
