(Received February 14th, 1972)

In contrast to the ready displacement of ethylene from certain square planar rhodium(I) ethylene complexes<sup>1-5</sup> the related  $\pi$ -cyclopentadienyldiethylenerrhodium(I) compound<sup>6</sup>,  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>, is inert to substitution by ligands such as triphenylphosphine, carbon monoxide and cyanide ion<sup>2</sup>. This difference has been attributed to the fact that in  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub> the metal can be regarded as having an inert gas configuration whereas the 16e square-planar rhodium(I) complex has a vacant orbital available to the incoming ligand<sup>2</sup>.

Ethylene is, however, readily displaced from  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub> by ligands such as SO<sub>2</sub> and tetracyanoethylene which have Lewis acid character and the metal is believed to act as the donor atom<sup>2</sup>. Recently the complex  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub>·HgCl<sub>2</sub> has been reported<sup>7</sup>, and the Lewis basicity of transition metals is well established<sup>8,9</sup>.

We have found that fluorophosphines, L, which have acceptor properties<sup>10,11</sup> (e.g., PF<sub>3</sub> forms a 1/1 complex with Me<sub>3</sub>N at low temperature)<sup>12</sup>, also readily displace ethylene from  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub> under mild conditions affording high yields of the yellow  $\pi$ -cyclopentadienylbis(fluorophosphine)rhodium(I) complexes,  $\pi$ -C<sub>5</sub>H<sub>5</sub>RhL<sub>2</sub> (I).

(I)

(L = PF<sub>3</sub>, CF<sub>3</sub>PF<sub>2</sub>, CCl<sub>3</sub>PF<sub>2</sub>, CCl<sub>2</sub>HPF<sub>2</sub>, Me<sub>2</sub>NPF<sub>2</sub>, (CF<sub>3</sub>)<sub>2</sub>PF)

(I) (L = PF<sub>3</sub>) has recently been synthesised from [RhCl(PF<sub>3</sub>)<sub>2</sub>]<sub>2</sub> and NaC<sub>5</sub>H<sub>5</sub><sup>13</sup>. The failure of carbon monoxide to displace ethylene from  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub><sup>2</sup> suggests that CO has weaker acceptor properties than fluorophosphines<sup>10,11</sup>.

As in the case of the ethylene- $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)<sub>2</sub> system, no exchange is observed between free and coordinated PF<sub>3</sub> in  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(PF<sub>3</sub>)<sub>2</sub><sup>13</sup>, whereas PF<sub>3</sub> and [RhCl(PF<sub>3</sub>)<sub>2</sub>]<sub>2</sub> readily undergo rapid intermolecular exchange<sup>13,14</sup>. Similarly no evidence was found for the intermediate  $\pi$ -C<sub>5</sub>H<sub>5</sub>Rh(C<sub>2</sub>H<sub>4</sub>)(PF<sub>3</sub>) when a solution of equimolar amounts of

$\pi\text{-C}_5\text{H}_5\text{Rh}(\text{C}_2\text{H}_4)_2$  and  $\pi\text{-C}_5\text{H}_5\text{Rh}(\text{PF}_3)_2$  was heated at  $60^\circ$ , in sharp contrast to the immediate formation of  $[\text{RhCl}(\text{C}_2\text{H}_4)(\text{PF}_3)]_2$  when solutions of  $[\text{RhCl}(\text{C}_2\text{H}_4)_2]_2$  and  $[\text{RhCl}(\text{PF}_3)_2]_2$  were mixed at room temperature<sup>15</sup>.  $\pi$ -Allylic trifluorophosphinerhodium(I) complexes, e.g.,  $\pi$ -allyl  $\text{Rh}(\text{PF}_3)_3$ , (all =  $\text{C}_3\text{H}_5$ ;  $\text{C}_4\text{H}_7$ ;  $\text{C}_6\text{H}_9$ ) undergo phosphine exchange via a dissociative mechanism<sup>16</sup>.

Ethylaminobis(difluorophosphine),  $\text{EtN}(\text{PF}_2)_2$ , which acts as a bidentate ligand towards Group VI metals<sup>17</sup> rapidly reacts with  $\pi\text{-C}_5\text{H}_5\text{Rh}(\text{C}_2\text{H}_4)_2$  at room temperature to yield rather unexpectedly  $\pi\text{-C}_5\text{H}_5\text{Rh}[\text{EtN}(\text{PF}_2)_2]_2$ .  $^{19}\text{F}$  NMR studies establish the presence of coordinated and uncoordinated  $\text{PF}_2$  groups in this complex in accordance with structure (II).

The identity of the complexes of type (I) is confirmed by their characteristic  $^{19}\text{F}$  NMR spectra which are typical of the X part of an  $[\text{X}_r\text{A}]_2$  spin system, (X = fluorine, A = phosphorus)<sup>17, 18, 19</sup>, each line being further split into a 1/1 doublet by the  $^{103}\text{Rh}$  nucleus ( $I \frac{1}{2}$ , 100% natural abundance). These NMR spectra will be discussed in detail in a later publication<sup>20</sup>
