(Received December 2nd, 1975)

### Summary

The compounds  $\text{Cp}_2\text{VR}$  ( $\text{R} = \text{CH}_3, \text{C}_2\text{H}_5, n\text{-C}_3\text{H}_7, n\text{-C}_4\text{H}_9, n\text{-C}_5\text{H}_{11}, \text{CH}_2\text{C}(\text{CH}_3)_3$  or  $\text{CH}_2\text{Si}(\text{CH}_3)_3$ ) have been prepared from  $\text{Cp}_2\text{VCl}$  and  $\text{RMgX}$  in *n*-pentane. The air-sensitive compounds are stable at room temperature, but decompose between 65 and 138°C. The thermal stability decreases in the order  $\text{R} = \text{CH}_3 \sim \text{CH}_2\text{Si}(\text{CH}_3)_3 > \text{C}_2\text{H}_5 > \text{CH}_2\text{C}(\text{CH}_3)_3 > n\text{-C}_5\text{H}_{11} > n\text{-C}_4\text{H}_9 > n\text{-C}_3\text{H}_7$ . Compounds with  $\text{R} = i\text{-C}_3\text{H}_7$  or  $t\text{-C}_4\text{H}_9$  could not be obtained.

### Introduction

Recent investigations on the thermal decomposition of dicyclopentadienyl derivatives of Ti and V viz.  $\text{Cp}_2\text{TiR}_2$  ( $\text{R} = \text{aryl}$  or  $\text{benzyl}$ ) [1,2],  $\text{Cp}_2\text{TiR}$  ( $\text{R} = \text{aryl}$  or  $\text{benzyl}$ ) [3] and  $\text{Cp}_2\text{VR}$  ( $\text{R} = \text{aryl}$ ) [4] showed some interesting properties of the Cp ligands. Substitution of a hydrogen atom of the Cp ligand and formation of  $\text{Cp}(\text{C}_5\text{H}_4\text{R})\text{V}$  compounds was observed for  $\text{Cp}_2\text{VR}$  together with the abstraction of hydrogen from these ligands and formation of  $\text{RH}$ . A similar study of the corresponding alkyl compounds  $\text{Cp}_2\text{VR}$  seemed interesting, but little is known about these compounds. The compounds  $\text{Cp}_2\text{VR}$  with  $\text{R} = \text{CH}_3, \text{CH}_2\text{C}_6\text{H}_5$  have been reported by De Liefde Meijer, who could not, however, isolate  $\text{Cp}_2\text{VC}_2\text{H}_5$ , probably because of its marginal thermal stability [5]. On the other hand, a number of allyl compounds  $\text{Cp}_2\text{VR}$ , stable at room temperature, have been described by Siegert [6]. This prompted us to reinvestigate the preparation of  $\text{Cp}_2\text{VR}$  compounds with  $\text{R} = \text{CH}_3, \text{C}_2\text{H}_5, n\text{-C}_3\text{H}_7, i\text{-C}_3\text{H}_7, n\text{-C}_4\text{H}_9, t\text{-C}_4\text{H}_9, n\text{-C}_5\text{H}_{11}, \text{CH}_2\text{C}(\text{CH}_3)_3$  and  $\text{CH}_2\text{Si}(\text{CH}_3)_3$ . The results are described below.

## Experimental

### General remarks

All experiments were carried out under nitrogen, using Schlenk-type glassware. Solvents were distilled and dried over sodium wire prior to use. Alkyl halides for Grignard reagents were commercially obtained and used without further purification.  $\text{Cp}_2\text{VCl}$  was prepared from  $\text{VCl}_3 \cdot 3\text{THF}$  (THF = tetrahydrofuran) and  $\text{CpNa}$  in THF and purified by sublimation ( $160^\circ\text{C}$ , 0.1 mmHg).

Elemental analyses were performed at the Microanalytical Department of this University under the supervision of Mr. A. F. Hamminga. IR spectra (Nujol) were obtained using a Hitachi EPI-G spectrophotometer; UV visible spectra were recorded with a Perkin-Elmer EPS-3T spectrophotometer. Mass spectra were recorded by Mr. A. Kiewiet on an AEI MS9 instrument. Magnetic susceptibilities (between 100–300 K) were determined by Miss H. Scholtens by the Faraday method. Melting points and decomposition temperatures were measured using a silicone oil bath.

### Synthesis of $\text{Cp}_2\text{VR}$ with $R = \text{CH}_3, \text{C}_2\text{H}_5, n\text{-C}_3\text{H}_7, n\text{-C}_4\text{H}_9, n\text{-C}_5\text{H}_{11}, \text{CH}_2\text{C}(\text{CH}_3)_3, \text{CH}_2\text{Si}(\text{CH}_3)_3$

All compounds were prepared in essentially the same way. The synthesis of  $\text{Cp}_2\text{V-n-C}_3\text{H}_7$  is described in detail; experimental and analytical data for the other compounds are given in Table 1.

*Preparation of n-propyldicyclopentadienylvanadium.*  $\text{Cp}_2\text{VCl}$  (2.75 g, 12.7 mmol) and 100 ml of n-pentane were stirred at  $0^\circ\text{C}$  and  $n\text{-C}_3\text{H}_7\text{MgBr}$  in ether (12.4 ml, 12.8 mmol) was added dropwise in 0.25 h. Stirring ( $0^\circ\text{C}$ ) was continued until all the  $\text{Cp}_2\text{VCl}$  had disappeared. The dark-green solution was filtered and slowly cooled to  $-78^\circ\text{C}$ . Black crystals separated. The mother liquor

<sup>a</sup> Reaction at  $0^\circ\text{C}$ . <sup>b</sup> Reaction at room temperature.

was removed and the product was washed twice (at  $-78^{\circ}\text{C}$ ) with 30 ml of *n*-pentane. After drying in vacuo 1.80 g (8.06 mmol, 63%) was isolated and sealed in ampoules, Table 1.

*Attempted preparation of alkylcyclopentadienylvanadium compounds with alkyl = *i*-propyl, *t*-butyl*

The reaction of  $\text{Cp}_2\text{VCl}$  with  $i\text{-C}_3\text{H}_7\text{MgCl}$  (and also with  $t\text{-C}_4\text{H}_9\text{MgBr}$ ) under the conditions described above, resulted in the formation of a violet solution from which only  $\text{Cp}_2\text{V}$  (IR, subl.  $80^{\circ}\text{C}$ , 0.1 mmHg) was obtained. The yields were 60 and 36% respectively.

**Results and discussion**

The very air-sensitive compounds  $\text{Cp}_2\text{VR}$  ( $\text{R} = \text{CH}_3, \text{C}_2\text{H}_5, n\text{-C}_3\text{H}_7, n\text{-C}_4\text{H}_9, n\text{-C}_5\text{H}_{11}, \text{CH}_2\text{C}(\text{CH}_3)_3, \text{CH}_2\text{Si}(\text{CH}_3)_3$ ) were obtained in good yield according to

( $\text{X} = \text{Cl}, \text{Br}$ )

eq. 1. The compounds were obtained analytically pure by recrystallization from *n*-pentane.

Elemental analyses, physical and chemical properties are in agreement with the formulation as  $\text{Cp}_2\text{VR}$ .

The IR spectra are all very similar and show absorptions due to  $\pi$ -bonded cyclopentadienyl groups at 3100, 1120, 1020, 1010, 800  $\text{cm}^{-1}$  [7]. Absorptions due to the  $\sigma$ -bonded alkyl group partly coincide with those of Nujol. For  $\text{Cp}_2\text{VCH}_2\text{Si}(\text{CH}_3)_3$ , the alkyl group shows characteristic absorptions at 1250, 1240, 852, 842, 740, 713, and 675  $\text{cm}^{-1}$ . A weak absorption in the range 465–440  $\text{cm}^{-1}$  was observed for a number of compounds and is assigned to a V–C stretching frequency [8]. The IR spectra of  $\text{Cp}_2\text{VCH}_2\text{Si}(\text{CH}_3)_3$  and  $\text{Cp}_2\text{VCH}_2\text{C}(\text{CH}_3)_3$  are almost identical with those of the analogous Ti compounds [8,9] and suggest a close structural relationship.

The electronic spectra (*n*-pentane, 340–1000 nm) of all compounds (except  $\text{R} = \text{CH}_2\text{Si}(\text{CH}_3)_3$ ) show three absorptions: at 720–730 nm ( $\epsilon \sim 90 \text{ l mol}^{-1} \text{ cm}^{-1}$ ), at 530–540 nm ( $\epsilon \sim 55 \text{ l mol}^{-1} \text{ cm}^{-1}$ ) and at 430–440 nm ( $\epsilon \sim 120 \text{ l mol}^{-1} \text{ cm}^{-1}$ ). These values are similar to those reported for  $\text{Cp}_2\text{VCH}_3$  and  $\text{Cp}_2\text{VC}_2\text{H}_5$  [5]. For  $\text{R} = \text{CH}_2\text{Si}(\text{CH}_3)_3$  the absorptions are shifted to longer wavelengths (760, 570 and 455 nm).

The magnetic properties of the compounds (Curie–Weiss behaviour between 100–300 K, magnetic moment close to the spin-only value of 2.83 BM,  $\text{R} = n\text{-C}_3\text{H}_7$ : 2.94 BM,  $\text{R} = \text{CH}_2\text{Si}(\text{CH}_3)_3$ : 2.63 BM), are as expected for vanadium(III) compounds.

The mass spectra (recorded for  $\text{R} = n\text{-C}_3\text{H}_7$  and  $\text{CH}_2\text{Si}(\text{CH}_3)_3$ ) show low-intensity signals due to the parent ions and intense peaks ascribed to  $\text{Cp}_2\text{V}^+$  and to its degradation products, indicating facile splitting of the V–alkyl bond.

The  $\text{Cp}_2\text{V}$  entity is quite stable, but the V–C  $\sigma$ -bond is easily split by HCl and  $\text{Br}_2$  (eq. 3,4):

The compounds discussed above are thermally quite stable and can be handled at room temperature. They all melt at the temperatures given and decompose at higher temperatures (Table 1). Assuming that the failure to prepare the compounds with  $\text{R} = \text{i-C}_3\text{H}_7$  and  $\text{t-C}_4\text{H}_9$  is due to their low thermal stability, the stability order is  $\text{R} = \text{CH}_3 \sim \text{CH}_2\text{Si}(\text{CH}_3)_3 > \text{C}_2\text{H}_5 > \text{CH}_2\text{C}(\text{CH}_3)_3 > \text{n-C}_5\text{H}_{11} > \text{n-C}_4\text{H}_9 > \text{n-C}_3\text{H}_7 > \text{t-C}_4\text{H}_9, \text{i-C}_3\text{H}_7$ . The high stability of the ethyl compound is quite unexpected, and cannot be explained at present. With the exception of  $\text{R} = \text{C}_2\text{H}_5$ , the stability seems to correlate with the total number of  $\beta$ -hydrogen atoms in the alkyl group, but the possibility that the thermal stability is mainly governed by the steric properties of the alkyl groups cannot be excluded. Coordinating solvents, such as ethers [5], decrease the thermal stability of the compounds  $\text{Cp}_2\text{VR}$ . For  $\text{R} = \text{CH}_3, \text{CH}_2\text{C}(\text{CH}_3)_3, \text{CH}_2\text{Si}(\text{CH}_3)_3$ , the yields were the same whether the synthesis was carried out in diethyl ether or in n-pentane. For the other compounds, vanadocene was the only product obtained in diethyl ether; a result which is in agreement with the experiments of De Liefde Meijer [5].

The thermal decomposition of the compounds  $\text{Cp}_2\text{VR}$  is now being studied and will be described in a forthcoming paper.
