(Received August 20th, 1981)

### Summary

The IR spectrum of 1-methyl, 1-trideuteromethyl-1-silaethylene,  $\text{CH}_3(\text{CD}_3)\text{-Si}=\text{CH}_2$ , formed in the gas phase by vacuum pyrolysis of the corresponding monosilacyclobutane has been recorded in an argon matrix at 10 K. The attribution of the spectral bands to the unstable species was carried out using the dependence of the spectra on temperature and pressure in the pyrolysis zone or on the matrix temperature. A possible assignment of some bands to the  $\nu(\text{Si}=\text{C})$  and  $\rho(\text{CH}_2)$  vibrations is discussed.

### Introduction

1,1-Dimethyl-1-silaethylene (I) is the first molecule with an unsaturated carbon–silicon bond whose existence has been proved by physical methods: at first for  $\text{I-}d_0$  from the infrared spectrum in an inert matrix at 10 K [1,2] and then with mass spectrometry [3] and electron diffraction [4] techniques. The matrix IR spectra of the deuterated derivative  $(\text{CD}_3)_2\text{Si}=\text{CH}_2$  ( $\text{I-}d_6$ ) were obtained later, simultaneously and independently by us [5–9] and by Guselnikov et al. [10–13]. Besides, Auner and Grobe have claimed IR-spectroscopic detection of  $\text{I-}d_0$  without a use of an inert matrix at 80 K [14].

The reported vibration frequencies of the  $\text{I-}d_0$  and  $\text{I-}d_6$  molecules differ substantially in the publications of the three-above-mentioned research groups. In this connection the present study was started to obtain additional information on the vibrational spectrum of I, including frequency shifts due to deuteration for the  $\text{CH}_3(\text{CD}_3)\text{Si}=\text{CH}_2$  ( $\text{I-}d_3$ ) molecule. Another goal was a thorough comparison of all vibrational data for  $\text{I-}d_0$  and  $\text{I-}d_6$ ; this problem is of great importance for correct assignment of the frequencies to the normal vibration modes of the molecule I.

Vacuum pyrolysis ( $10^{-2}$ – $10^{-4}$  Torr, 650–1000°C) of 1,1-dimethyl-1-sila-

cyclobutane (II- $d_3$ ) was chosen as a source of the I- $d_3$  species (by analogy with the pyrolysis of II- $d_0$  [15]), the final products of the reaction being  $C_2H_4$  and 1,1,3,3-tetramethyl-1,3-disilacyclobutane- $d_6$  (III- $d_6$ ). The IR spectrum of the intermediate I- $d_3$  thus formed may be obtained by its isolation in an Ar-matrix at 10–15 K. A similar technique was used earlier by us to stabilize and investigate I- $d_0$  and I- $d_6$  silaolefins [2,9]. Preliminary results of the study were published previously [8].

## Experimental

The parent compound II- $d_3$  was prepared by reaction of  $\text{CD}_3\text{MgI}$  with 1-methyl, 1-chloro-1-silacyclobutane which was synthesized by cyclization of

<sup>a</sup> The mass spectrum was obtained at an ionizing energy of 70 eV on an Varian MAT CH-6 instrument.

$\gamma$ -chloropropylmethyldichlorosilane in the presence of Mg. The formal dimer of I- $d_3$  — disilacyclobutane, III- $d_6$  — was singled out from the final products of pyrolysis of II- $d_3$ . All the samples were purified by preparative GLC and then by bulb-to-bulb vacuum distillation. Their purity was determined from the GC-MS data to be higher than 99%. The mass spectrum of II- $d_3$  is given in Table 1.

The pyrolytic products of II- $d_3$  were trapped at 10 K together with an excess of argon (1000—5000 : 1) on a CsI optical window cooled by a continuous flow of liquid helium. The IR spectra were recorded on a Hitachi-Perkin-Elmer 225 spectrophotometer, wavenumber accuracy being  $\pm 0.2 \text{ cm}^{-1}$ . Annealing of the matrix and the trapped pyrolysis products was performed by a steady change in a coolant flow. As a result, the temperature of the cold window rose from 10 up to 35—40 K followed by recooling down to 10 K and recording a new IR spectrum.

## Results and discussion

The matrix IR spectra of the parent compound II- $d_3$  (Fig. 1a), those of the final dimeric product III- $d_6$  (Fig. 1d) and the pyrolysis products of II- $d_3$  (Fig. 1b) were recorded in the course of the current work. The corresponding wavenumber values are given in Table 2.

### *The IR spectrum of $\text{CH}_3(\text{CD}_3)\text{Si}=\text{CH}_2$ (I- $d_3$ )*

In the spectrum of the products of the pyrolysis (840°C) one can observe the bands of ethylene and the dimer III- $d_6$  and those of the initial compound II- $d_3$ , partially converted. The very weak bands belong to the following molecules:  $\text{CH}_4$  (1304.5  $\text{cm}^{-1}$ ),  $\text{C}_2\text{H}_2$  (736.2  $\text{cm}^{-1}$ ),  $\text{C}_2\text{HD}$  (682.0 and 518.0  $\text{cm}^{-1}$ ) and  $\text{C}_2\text{D}_2$  (541.3  $\text{cm}^{-1}$ ) [9,16]. The well-known double band of  $\text{CO}_2$  at 661.7—663.2  $\text{cm}^{-1}$  may also be seen in the matrix spectra.

In addition, we have discovered the bands at 606.0, 755.2, 817.5, 975.5, 1016.5, 1025.0, 1259.5  $\text{cm}^{-1}$  and three weaker shoulder-type bands at 749.0, 1003.0 and 1006.0  $\text{cm}^{-1}$  in this spectrum (Fig. 1b). All these new features do not belong to the molecules mentioned above.

A steady heating of a matrix up to the diffusion temperatures is often used to distinguish the bands belonging to the unstable intermediates. Earlier, this way the I- $d_0$  and I- $d_6$  species were found to form the dimers (corresponding to 1,3-disilacyclobutanes) under the diffusion conditions [9]. The present experiments have demonstrated a synchronous decrease in intensity for seven spectral bands (at 606.0, 755.2, 817.5, 975.5, 1016.5, 1025.0 and 1259.5  $\text{cm}^{-1}$ ) during the matrix warming from 10 to 35—40 K. Simultaneously, the bands (at 591.0, 674.0, 770.6, 814.9, 841.3, 861.0, 934.6 and 998.5  $\text{cm}^{-1}$ ) of the compound III- $d_6$  (the dimer of I- $d_3$ ) grew (Fig. 1c). On the other hand, the features at 749.0, 1003.0 and 1006.0  $\text{cm}^{-1}$  did not disappear when the matrix was heated.

To verify the assignment of the indicated bands to an unstable species we have studied the effect of pressure and/or temperature changes in the pyrolysis zone on a matrix IR spectrum of the pyrolysis products. The rise in pressure (that is the increased number of the intermolecular collisions) should favour

secondary reactions of intermediates in the gas phase. Indeed, the intensities of seven IR bands were significantly lower at pyrolysis pressure of  $10^{-1}$ —1 Torr whereas the intensities of the dimer III-*d*<sub>6</sub> bands increased considerably. This allows us to assign the seven bands mentioned to silaethylene, CH<sub>3</sub>(CD<sub>3</sub>)Si=CH<sub>2</sub> (I-*d*<sub>3</sub>), which reacts with an environment (the parent compound or another I-*d*<sub>3</sub> species) to form the dimer I-*d*<sub>6</sub>, just as during the matrix warming.

Fig. 2. The IR spectrum of the pyrolysis products of II-*d*<sub>3</sub> (970°C,  $5 \times 10^{-3}$  Torr) in an Ar matrix at 10 K.

The formation of the dimer III- $d_6$  was found even at 10–15 K in the case of insufficient argon concentration in a matrix which emphasizes the high reactivity of silaethylene I (cf. ref. 9). This observation agrees with the complete absence of the I- $d_3$  bands in the spectra of the pyrolysis products frozen at 77 K without a matrix. We recorded the bands of the stable compounds II- $d_3$  and III- $d_6$  only under such conditions.

The IR bands of silaethylene I- $d_3$  including the most intensive 755.2, 817.5 and 1016.5  $\text{cm}^{-1}$  bands were almost missing in the spectra if the pyrolysis temperature was raised up to 900–1000°C (Fig. 2). We have previously observed similar extensive fragmentation of II- $d_0$  and II- $d_6$  silacyclobutanes and probably, I- $d_0$  and I- $d_6$  silaethylenes in vacuum pyrolysis at 1000°C [9]. It is worth mentioning that the intensities of the 749, 1003 and 1006  $\text{cm}^{-1}$  bands have, on the contrary, increased in the spectrum of Fig. 2 in comparison with Fig. 1b, proving once more their assignment to stable molecules and not to I- $d_3$ . In Fig. 2 the strong bands of  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{HD}$ ,  $\text{C}_2\text{D}_2$  and  $\text{CH}_4$  have appeared. Their growth gives another evidence of nonselective dissociation of II- $d_3$  at temperatures above 900°C.

A matter of interest is the elimination of  $\text{C}_2\text{HD}$  and  $\text{C}_2\text{D}_2$  from the parent silacyclobutane II- $d_3$ , which does not contain any C–C bond to a deuterated carbon atom. The intramolecular pyrolytic rearrangement involving formation of  $\text{C}_2\text{HD}$  and  $\text{C}_2\text{D}_2$  molecules may be compared with the elimination of the neutral acetylenes  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{HD}$  and  $\text{C}_2\text{D}_2$  under electron impact fragmentation of II- $d_0$ , II- $d_3$  and II- $d_6$  compounds [17].

#### Analysis of the IR spectra of the I- $d_0$ , I- $d_3$ and I- $d_6$

The vibrational frequencies of the I- $d_3$  molecule obtained in the present study should be correlated with the respective data for I- $d_0$  and I- $d_6$  silaethylenes. The differences between the frequency values from three literature sources, however, are rather substantial (Table 3).

<sup>a</sup> The frequency values assigned probably by mistake to silaethylene are discussed in the text.

$(CH_3)_2Si=CH_2$  (*I-d*<sub>0</sub>). We found six bands of the *I-d*<sub>0</sub> molecule in the matrix IR spectrum as early as 1976–1977 [1,2]. Later, eight bands were reported for *I-d*<sub>0</sub> [10–13], five of them agreed well with our data (Table 3).

Three other bands at 696, 932 and 992  $cm^{-1}$  reported [10–13] have been shown to belong to the stable molecules of the dimer *III-d*<sub>0</sub> and propylene rather than to silaethylene *I-d*<sub>0</sub> [9]. In particular, this conclusion results from the alteration of the ratio of the mentioned bands intensities in various experiments at 10 K [9,13]. We also observed a similar pattern warming the matrix up to 35–40 K.

Recently, the IR spectrum has been obtained after the pyrolysis products of *II-d*<sub>0</sub> had been frozen without an inert matrix at 80 K [14]. The band at 1156  $cm^{-1}$  in this spectrum has been assumed to belong to the Si=C stretching vibration of the *I-d*<sub>0</sub> species. However, a similar band near 1156  $cm^{-1}$  is seen in the IR spectrum of the initial compound *II-d*<sub>0</sub> [14, Fig. 1]. We observed the 1156  $cm^{-1}$  band at 77 K (1159  $cm^{-1}$  in an Ar matrix at 10 K) in the spectra of an inadequately purified sample of *II-d*<sub>0</sub> and in those of its pyrolysis products. This spectral band is completely absent when the *II-d*<sub>0</sub> sample is purified by preparative GLC [9]. Probably the band at 1156  $cm^{-1}$  belongs to an impurity and not to silaethylene *I-d*<sub>0</sub>.

$(CD_3)_2Si=CH_2$  (*I-d*<sub>6</sub>). The matrix IR spectra of the *I-d*<sub>6</sub> molecule have been obtained by us [5–9] and by others [10–13] (Table 3). However, the 543, 683, 718, 722 and 891  $cm^{-1}$  bands given in refs. 10–13 have been shown not to disappear after the matrix warming [9]. What is more, these five bands increase markedly in intensity if the temperature of vacuum pyrolysis approaches 1000°C, just as the strongest bands of *I-d*<sub>6</sub> species (near 580, 769 and 1015  $cm^{-1}$ ) are practically missing in the same spectrum [9]. The other two bands at 929 and 985  $cm^{-1}$  have been assigned [10–13] to the *I-d*<sub>6</sub> molecule, but they do not disappear on the matrix warming either. These band positions are close to the vibrational frequencies of the stable molecules which can be present in the reaction mixture [10–13]: propylene (931.0  $cm^{-1}$  [18]), the dimer *III-d*<sub>12</sub> (932.9  $cm^{-1}$  [9]) and the starting material 1,1,3-trimethyl-1-silacyclobutane-*d*<sub>6</sub> (of *II-d*<sub>6</sub>). The last two compounds have the corresponding frequency values of 985 and 988  $cm^{-1}$  under a M/R (matrix gas to reagent) ratio less than 500.

Thus one can infer that seven bands out of ten indicated [10–13] for silaethylene *I-d*<sub>6</sub> (Table 3) belong to stable molecules.

$CH_3(CD_3)Si=CH_2$  (*I-d*<sub>3</sub>). For silaethylene *I-d*<sub>3</sub> we have discovered several IR bands in the present study (Tables 2 and 3). It is of interest to analyse their possible assignments to the normal vibrations of the molecule *I-d*<sub>3</sub>. Earlier, the intense 1003.5  $cm^{-1}$  band had been assigned to the Si=C bond stretching vibration in the *I-d*<sub>0</sub> molecule [5–9, 10–13]. It is known that the intensity of the C=C stretching vibration band in an IR spectrum of isobutylene does not change much on deuteration of the methyl groups [19]. Analogous deuteration of the methyl groups in the *I-d*<sub>0</sub> molecule should not cause a very significant shift in the Si=C stretching frequency. Therefore, the corresponding band in the IR spectra of *I-d*<sub>3</sub> or *I-d*<sub>6</sub> should be positioned in 950–1150  $cm^{-1}$  region [6,12,13]. In the spectrum of *I-d*<sub>3</sub> one can see three such bands at 975.5, 1016.5, and 1025.0  $cm^{-1}$ , of which the 1016.5  $cm^{-1}$  band is much stronger than two

others. Probably, this band can be assigned to the stretching Si=C vibration in I- $d_3$ .

The strong band of the out-of-plane vibration of the =CH<sub>2</sub> fragment,  $\rho(\text{CH}_2)$ , is characteristic of  $\alpha$ -olefines, CH<sub>3</sub>CH=CH<sub>2</sub>, (CH<sub>3</sub>)<sub>2</sub>C=CH<sub>2</sub> and others. The intensity of this band does not vary much on deuteration of a nearby methyl group. Consequently, the most intense 817.5 cm<sup>-1</sup> band in the spectrum of I- $d_3$  may belong to the  $\rho(\text{CH}_2)$  vibrational mode, its counterpart in the I- $d_0$  molecule being the 825.2 cm<sup>-1</sup> band [9].

The vibrational frequencies of I- $d_3$  found in the present work have been used for the force field analysis of the silaethylene I molecule. The basic inferences from the calculations have been published by us previously [5–9,20]. More detailed results of the force field study are described separately [21].
