(Received April 29th, 1982)

Summary

The decomposition of  $\eta^6$ -(2-lithiochlorobenzene)tricarbonylchromium(0) (I) was found to follow first order kinetics with  $k_{\text{dec}} = 5.1 \times 10^{-3} \text{ min}^{-1}$  at  $0^\circ\text{C}$ , the half life of I being 136 min at  $0^\circ\text{C}$ . While this dependence strongly suggests intermediacy of  $\eta^6$ -(benzyne)tricarbonylchromium, trapping experiments were successful in only low yield.

---

Coordination of a tricarbonylchromium unit to an arene enhances the kinetic acidity of the ring C—H bonds [1]. Metalation with alkyl lithium reagents produces  $\eta^6$ -(lithioarene)tricarbonylchromium(0) complexes which have been characterized spectroscopically [1e] and have been trapped by reaction with electrophiles [1]. Parallel with directing effects observed in the metalation of uncomplexed arenes,  $\eta^6$ -anisole and  $\eta^6$ -halobenzene ligands are metalated in the *ortho* position [1]. The increased rate of deprotonation due to the  $\text{Cr}(\text{CO})_3$  unit allows direct formation of  $\eta^6$ -(2-lithiochlorobenzene)tricarbonylchromium(0) (I) and  $\eta^6$ -(2-lithiofluorobenzene)tricarbonylchromium(0) (II) in high efficiency; parallel reactions with free chlorobenzene and fluorobenzene are not possible. In addition, the trapping of I with electrophiles at  $-20^\circ\text{C}$  [1a] suggested a thermal stability for I much higher than that of 2-lithiochlorobenzene, where decomposition within minutes at  $-78^\circ\text{C}$  has been noted [2]. This decomposition produces 1,2-dehydrobenzene, as evidenced by characteristic *in situ* trapping reactions [3]. Neither the rate nor the mode of decomposition of I or II has been studied; a benzyne complex III is predicted, in a coordination mode for the benzyne ligand not previously observed [4]. Here we report efforts to define the thermal stability of I and to test for the presence of III.

\*On leave from Chalmers University of Technology, S-41296 Göteborg (Sweden).

We have studied the decomposition of I, between  $-50^{\circ}\text{C}$  and  $+33^{\circ}\text{C}$  (ether solvent). In some cases, furan was added as a trapping agent for a benzyne complex, after lithiation appeared to be complete. For example, reaction of  $\eta^6$ -(chlorobenzene)tricarbonylchromium(0) with butyllithium at  $-35^{\circ}\text{C}$  for 15 min, followed by addition of  $\text{CO}_2$  gives  $\eta^6$ -(2-chlorobenzoic acid)tricarbonylchromium(0) in 98% yield [3a]. If the solution is allowed to warm to  $0^{\circ}\text{C}$  decomposition of I proceeds slowly; the clear orange solution turns dark brown and a solid forms. After ca. 1 h at  $25^{\circ}\text{C}$ , addition of aqueous HCl regenerates  $\eta^6$ -(chlorobenzene)tricarbonylchromium(0), 44% recovery. Oxidation of the remainder of the crude product with excess iodine gave a complex mixture of free arenes; the major component was identified as 2-chlorobiphenyl by GC-MS analysis, but the yield was less than 5%. Under the same conditions but in the presence of excess furan, no new product incorporating the furan unit was detected by GC-MS. Heating the solution of I with excess furan in ether at reflux for 40 min led to complete disappearance of I and formation of a complex mixture. After oxidation with excess iodine, trituration with ether, and analysis of the ether soluble material (34% recovery based on chlorobenzene), showed 13 significant components. The major components were identified as naphthalene, 1-hydroxynaphthalene, 1,4-oxo-1,4-dihydronaphthalene, and 2-chlorobiphenyl, all of which can be attributed to a benzyne intermediate. However, the inefficient and unselective trapping does not establish the presence of complex III as a major intermediate.

TABLE 1

MONITORING OF THE DISAPPEARANCE OF *o*-LITHIOCHLOROBENZENETRICARBONYL-CHROMIUM(0)

Aliquot number	Time (min)	$\ln C_0/C$
1	13	0.28
2	20	0.43
3	35	0.51
4	55	0.55
5	80	0.67
6	110	0.85
7	140	0.95
8	200	1.16
9	265	1.38
10	330	1.75
11	405	2.11
12	545	2.96
13	640	3.79

Careful monitoring of the decomposition of I (0.1 M in ether) at  $0^{\circ}\text{C}$  ( $\pm 2^{\circ}$ ) showed first order dependence on the concentration of I. Aliquots of the solution were added to excess iodine and the amount of 2-chloriodobenzene (quantitative GC analysis using 1-methylnaphthalene as internal standard) formed was taken as a measure of  $\eta^6$ -(2-lithiochlorobenzene)tricarbonylchromium(0) remaining (Table 1). A plot of  $\ln C_0/C$  vs. time gave a slope of  $5.1 \times 10^{-3} \text{ min}^{-1}$  with a correlation coefficient of 0.984 over the range  $\ln C_0/C$  0.28 to 3.79. The half life for I at  $0^{\circ}\text{C}$  is 136 min. The stability of I

is strongly increased compared to *o*-chlorolithiobenzene and, while the benzyne III cannot be observed directly nor trapped efficiently, the simple first order decomposition of I is consistent with the intermediacy of III.
