(Received November 18th, 1983)

### Summary

The bridging vinyl clusters  $[\text{HOs}_3(\text{CH}=\text{CHR})(\text{CO})_{10}]$  ( $\text{R} = \text{H}$ ,  $\text{Ph}$ , or  $n\text{-Bu}$ ) react with  $\text{PMe}_2\text{Ph}$  to give the zwitterionic adducts  $[\text{HOs}_3(\text{CHCHRPM}_2\text{Ph})(\text{CO})_{10}]$  which contain  $\mu_2$ -alkylidene ligands. The adducts are not formed so readily when  $\text{R} = \text{Ph}$  or  $n\text{-Bu}$  but most readily when polar solvents are used. All three  $\text{CH}=\text{CHR}$  complexes add cyanide ion irreversibly to give the anionic clusters which were isolated as  $[\text{N}(\text{PPh}_3)_2][\text{HOs}_3(\text{CHCHRCN})(\text{CO})_{10}]$ . There is infrared evidence for the addition of various other anions. Acid reverses the addition of methoxide but  $\text{HCl}$  reacts with the cyanide adduct  $[\text{HOs}_3(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$  to give  $[\text{HOs}_3\text{Cl}(\text{CO})_{10}]$  and  $\text{EtCN}$ . No evidence for nucleophilic addition at  $[\text{HOs}_3(\text{PhC}=\text{CHPh})(\text{CO})_{10}]$  was obtained.

### Introduction

Nucleophilic addition at  $\eta$ -alkenes normally occurs only in cationic complexes or where the metal is in a fairly high oxidation state. With clusters, however, addition at unsaturated hydrocarbons occurs even with neutral compounds [1–4]. The first example to be reported was the addition of  $\text{PMe}_2\text{Ph}$  to  $[\text{Os}_3\text{H}(\mu\text{-CH}=\text{CH}_2)(\text{CO})_{10}]$  to give the zwitterionic  $\mu$ -alkylidene complex  $[\text{Os}_3\text{H}(\mu\text{-CHCH}_2\text{PMe}_2\text{Ph})(\text{CO})_{10}]$ , the structure of which has been established spectroscopically and by X-ray diffraction [3]. In this paper we report addition reactions of  $\text{PMe}_2\text{Ph}$  and other nucleophiles at  $\mu\text{-CH}=\text{CHR}$  ( $\text{R} = \text{H}$ ,  $n\text{-Bu}$ , or  $\text{Ph}$ ) complexes, extending earlier work on  $\text{PMe}_2\text{Ph}$  addition at the  $\text{CH}=\text{CH}_2$  complex.

### Results and discussion

*Dimethylphenylphosphine additions.*  $\text{PMe}_2\text{Ph}$  reacts readily with  $[\text{Os}_3\text{H}(\mu\text{-CH}=\text{CH}_2)(\text{CO})_{10}]$  (**1a**) in cyclohexane solution to give a precipitate of the adduct **2a**. The adduct is maintained on redissolving the crystals in chloroform and can be characterised by its  $^1\text{H}$  NMR and infrared spectra in that solution.  $\nu(\text{CO})$  frequen-

1a: R = H  
1b: R = Ph  
1c: R = <sup>n</sup>Bu

1d

2a: R = H  
2b: R = Ph  
2c: R = <sup>n</sup>Bu

3a: R = H  
3b: R = Ph  
3c: R = <sup>n</sup>Bu

cies are lower for **2a** than for **1a** because of the accumulation of negative charge at the metal atoms in the zwitterionic adduct. The addition of  $\text{PMe}_2\text{Ph}$  to cyclohexane solutions of compounds **1b** and **1c** does not lead to adduct formation. Instead slow substitution reactions take place leading to  $[\text{Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$  with alkene displacement. Interestingly this complex was obtained as two separable isomers which we believe to be the 1,2-isomer (previously formed directly from  $\text{PMe}_2\text{Ph}$  and tris-osmium dodecacarbonyl) [5] and a new 1,1-isomer as a minor product (see Experimental Section for spectroscopic details). The equilibrium for  $\text{PMe}_2\text{Ph}$  adduct formation is unfavourable in cyclohexane or dichloromethane and relatively slow alkene displacement then occurs. Alkene displacement is faster for **1c** than for **1b** and much faster for both of these than for **1a**. However, the adduct **2b** may be obtained as yellow crystals from polar solvents such as acetone. Redissolving crystals of **2b** in chloroform showed only the  $^1\text{H}$  NMR spectrum of  $\text{PMe}_2\text{Ph}$  and **1b**, while only partial dissociation occurred on redissolving in acetone. NMR spectra of **2b** and **2c** were therefore recorded in  $\text{CD}_3\text{COCD}_3$  in the presence of a small excess of  $\text{PMe}_2\text{Ph}$ ; no **1b** or **1c** were observed under these conditions. Thus the equilibria leading to adduct formation are suppressed by substituents at the carbon at which  $\text{PMe}_2\text{Ph}$  adds but are favoured by polar solvents. The  $^1\text{H}$  NMR spectra of compounds **2b** and **2c**, unlike that of **2a**, show diastereotopic  $\text{PMe}_2\text{Ph}$  groups since the phosphonium centre is attached to an asymmetric carbon atom.

No evidence for  $\text{PMe}_2\text{Ph}$  adduct formation was found at all for  $[\text{HOs}_3(\text{CPh}=\text{CHPh})(\text{CO})_{10}]$  (**1d**), even in polar solvents. Only the substitution products  $[\text{Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$  (again as isomers) were obtained. Although the carbon atom to be attacked is substituted in the same way as that of the  $\text{CH}=\text{CHPh}$  complex (**1b**), there is a good reason why the adduct is not formed. Complexes of

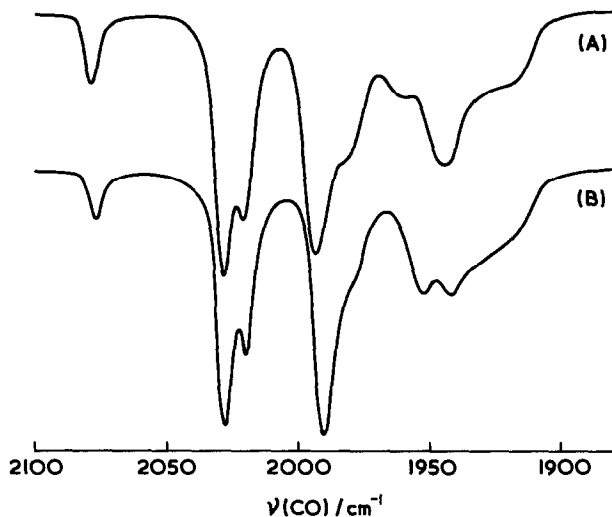

Fig. 1. Infrared spectra of ethanolic solutions of (A)  $[\text{Os}_3\text{H}(\text{CHCH}_2\text{PMe}_2\text{Ph})(\text{CO})_{10}]$  and (B)  $[\text{Os}_3\text{H}(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$ .

type  $[\text{HOs}_3(\mu\text{-vinyl})(\text{CO})_{10}]$  adopt one of two configurations; the  $\text{CPh}=\text{CHPh}$  complex has a different one to that of the  $\text{CH}=\text{CH}_2$  and  $\text{CH}=\text{CHEt}$  complexes (see structural formulae shown) [6–8]. The  $\text{CH}=\text{CHR}$  complexes ( $\text{R} = \text{H}, \text{Ph}, n\text{-Bu}, \text{Et}$ ) are almost certainly isostructural and different structurally from the  $\text{CPh}=\text{CHPh}$  complex. Nucleophilic addition of  $\text{PMe}_2\text{Ph}$  at complex **1d** would give an adduct in which the  $\text{CHPhPMe}_2\text{Ph}$  group would clash with an axial  $\text{CO}$  ligand of the  $\text{Os}(\text{CO})_4$  group.

**Anion additions.** Addition of potassium cyanide to the vinyl complexes **1a–1c** in ethanol gave an immediate reaction as indicated by the shift of  $\nu(\text{CO})$  absorptions to lower frequencies. The anionic products may be isolated by addition of  $[\text{N}(\text{PPh}_3)_2]\text{Cl}$ . The spectra around  $2000\text{ cm}^{-1}$  are very similar to those of the corresponding  $\text{PMe}_2\text{Ph}$  adducts (see Fig. 1). Thus the build-up of negative charge at the metal atoms is only very slightly greater, if at all, in the anion than in the zwitterionic  $\text{PMe}_2\text{Ph}$  adduct. The  $^1\text{H}$  NMR data (Table 2) are quite consistent with these complexes having structures directly related to that established for  $[\text{HOs}_3(\text{CHCH}_2\text{PMe}_2\text{Ph})(\text{CO})_{10}]$ , that is structure **3** illustrated. The spectrum of  $[\text{HOs}_3(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$  is particularly simple and clear in this respect. The additions to give the cyano compounds **3** are irreversible and the adducts fairly easy to isolate. However, with most other anions the formation of adducts was only inferred from changes in the  $\nu(\text{CO})$  spectra of solutions; the products could not be isolated.  $[\text{N}(\text{PPh}_3)_2][\text{HOs}_3(\text{CHCH}_2\text{OMe})(\text{CO})_{10}]$  was isolated in an impure state and was only characterised by its  $^1\text{H}$  NMR and infrared spectra (see Table 1). Additions of various anions to ethanolic solutions of  $[\text{HOs}_3(\text{CH}=\text{CH}_2)(\text{CO})_{10}]$  gave infrared spectra consistent with their addition. We cannot be entirely certain that  $[\text{HOs}_3(\text{CHCH}_2\text{OEt})(\text{CO})_{10}]^-$  is not formed in these cases, but the minor differences in the spectra (Table 1) suggest that the different anions,  $[\text{SC}_6\text{H}_4\text{Me-}p]^-$ ,  $\text{OH}^-$ ,  $\text{NEt}_2^-$ , are adding. In the case of  $\text{Et}_2\text{NH}$  addition we assume that the excess of base leads to  $[\text{Et}_2\text{NH}_2][\text{HOs}_3(\text{CHCH}_2\text{NEt}_2)(\text{CO})_{10}]$ . Slow reactions often follow these

additions. For example, compound **1a** reacts with Et<sub>2</sub>NH/NaOMe in refluxing methanol to give [HOs<sub>3</sub>(OMe)(CO)<sub>10</sub>] (22%), [HOs<sub>3</sub>(OH)(CO)<sub>10</sub>] (15%), as well as [HOs<sub>3</sub>(CHCH=NEt<sub>2</sub>)(CO)<sub>10</sub>] (5%). The last compound was previously reported to be formed by reactions of NEt<sub>3</sub> with [Os<sub>3</sub>(CO)<sub>10</sub>(MeCN)<sub>2</sub>] [9] but we do not yet understand how this compound is formed by loss of hydride from [HOs<sub>3</sub>(CHCH<sub>2</sub>NEt<sub>2</sub>)(CO)<sub>10</sub>]<sup>-</sup> which is presumably formed initially.

Tertiary amines do not add. Initially we thought that they did, since a solution of [HOs<sub>3</sub>(CH=CH<sub>2</sub>)(CO)<sub>10</sub>] in triethylamine gave a ν(CO) spectrum consistent with an adduct formation. However, if primary and secondary amine impurities and water are removed, the spectrum of the vinyl compound in NEt<sub>3</sub> is like that in other inert solvents. Addition of small amounts of Et<sub>2</sub>NH to an NEt<sub>3</sub> solution of the complex then leads to what we presume is [Et<sub>2</sub>NH][HOs<sub>3</sub>(CHCH<sub>2</sub>NEt<sub>2</sub>)(CO)<sub>10</sub>]. Use of PhNMe<sub>2</sub> as solvent gave a similar effect (Table 1).

No nucleophilic additions to [HOs<sub>3</sub>(CPh=CHPh)(CO)<sub>10</sub>] could be substantiated. Treatment of the compound with Me<sub>3</sub>NO leads to decarbonylation to give [H<sub>2</sub>Os<sub>3</sub>(μ<sub>3</sub>-PhC<sub>2</sub>Ph)(CO)<sub>9</sub>], in which case attack has occurred at CO [8]. The alkene PhCH=CHPh is displaced in many reactions of the vinyl compound; compound **1d** in moist acetone readily gives [HOs<sub>3</sub>(OH)(CO)<sub>10</sub>] while in CD<sub>3</sub>OD the cluster [DOs<sub>3</sub>(OCD<sub>3</sub>)(CO)<sub>10</sub>] is obtained.

*Protonation reactions.* An excess of CF<sub>3</sub>CO<sub>2</sub>H reacts with [HOs<sub>3</sub>(CH=CH<sub>2</sub>)(CO)<sub>10</sub>] in either CDCl<sub>3</sub> or CD<sub>2</sub>Cl<sub>2</sub> to give ethene and [HOs<sub>3</sub>(CF<sub>3</sub>CO<sub>2</sub>)(CO)<sub>10</sub>] (<sup>1</sup>H NMR identification). An intermediate was observed by <sup>1</sup>H NMR (singlets at δ 3.6 and -14.3) but this could not be characterised further.

Acidification of solutions of the adducts leads to two different types of reaction. Thus [HOs<sub>3</sub>(CHCH<sub>2</sub>OMe)(CO)<sub>10</sub>]<sup>-</sup> reacts initially with CF<sub>3</sub>CO<sub>2</sub>H to give [HOs<sub>3</sub>(CH=CH<sub>2</sub>)(CO)<sub>10</sub>] and MeOH and with an excess of the acid the reaction described above proceeds. [HOs<sub>3</sub>(CHCH<sub>2</sub>OMe)(CO)<sub>10</sub>]<sup>-</sup> is behaving as an activated ether and the nucleophilic addition of OMe<sup>-</sup> is reversed. On the other hand an

excess of HCl reacts with a chloroform solution of  $[\text{HOs}_3(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$  to give  $[\text{HOs}_3\text{Cl}(\text{CO})_{10}]$  and EtCN, identified by their NMR spectra. In this case acidolysis of the Os–C bonds has occurred as in the reactions of  $[\text{HOs}_3(\text{CHCH}_2\text{PMe}_2\text{Ph})(\text{CO})_{10}]$  with HCl in refluxing methanol which gives  $[\text{EtPMe}_2\text{Ph}]\text{Cl}$  [2]. Additions of  $\text{CF}_3\text{CO}_2\text{H}$  or  $\text{CH}_3\text{CO}_2\text{H}$  to  $[\text{HOs}_3(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$  give the corresponding compounds  $[\text{HOs}_3(\text{RCO}_2)(\text{CO})_{10}]$ .

Attempting to establish whether protonation occurred initially at the metal in these acidifications, we added stoichiometric amounts of  $\text{CF}_3\text{CO}_2\text{H}$  to  $\text{CDCl}_3$  solutions of  $[\text{HOs}_3(\text{CHCH}_2\text{PMe}_2\text{Ph})(\text{CO})_{10}]$  and  $[\text{HOs}_3(\text{CHCH}_2\text{CN})(\text{CO})_{10}]^-$  at different temperatures. Several new hydride NMR signals were observed indicating a mixture of hydrides, the composition of which varied with time. We do not have any evidence to identify these intermediates, but clearly the acidolysis occurs through several stages.

## Experimental

The complexes  $[\text{Os}_3\text{H}(\mu\text{-CH=CHR})(\text{CO})_{10}]$  (R = H [10], Ph [10], and n-Bu [11]) and  $[\text{Os}_3\text{H}(\mu\text{-CPh=CHPh})(\text{CO})_{10}]$  [10] were prepared by published procedures.

### Reactions of vinyl compounds with $\text{PMe}_2\text{Ph}$

(a)  $[\text{HOs}_3(\text{CH=CH}_2)(\text{CO})_{10}]$ . The addition has been described [1–3].

(b)  $[\text{HOs}_3(\text{CH=CHPh})(\text{CO})_{10}]$ .  $\text{PMe}_2\text{Ph}$  (0.050 cm<sup>3</sup>) was added to a solution of the  $\text{CH=CHPh}$  complex (0.040 g) in a mixture of dichloromethane (5 cm<sup>3</sup>) and nitromethane (5 cm<sup>3</sup>). The colour changed immediately from orange to yellow and the solvent was removed under vacuum to give a yellow oil. Crystallisation from acetone containing an excess of  $\text{PMe}_2\text{Ph}$  gave orange crystals of  $[\text{HOs}_3(\text{CHCHPhPMe}_2\text{Ph})(\text{CO})_{10}]$  (0.030 g, 66%). (Found: C, 28.8; H, 1.9.  $\text{C}_{28}\text{H}_{19}\text{O}_{10}\text{Os}_3\text{P}$  calcd.: C, 27.0; H, 1.8%).

A similar addition of  $\text{PMe}_2\text{Ph}$  (0.010 cm<sup>3</sup>) to the  $\text{CH=CHPh}$  compound (0.040 g) in cyclohexane (20 cm<sup>3</sup>) under nitrogen gave no initial reaction (the spectrum was unchanged around 2000 cm<sup>-1</sup>). Further  $\text{PMe}_2\text{Ph}$  (0.040 g) was added. After 5 days the solution was evaporated to give an orange oil which was separated by TLC (silica, eluant = petroleum ether/dichloromethane mixture, 9/1 by volume) to give starting material (0.002 g),  $[\text{1,1-Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$  (0.014 g, 31%), and  $[\text{1,2-Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$ . The 1,2-isomer has been formed by reaction of  $[\text{Os}_3(\text{CO})_{12}]$  with  $\text{PMe}_2\text{Ph}$  [5], while the 1,1-isomer can be alternatively formed by reaction of  $\text{PMe}_2\text{Ph}$  with  $[\text{Os}_3(\text{CO})_{10}(\text{diene})]$  (diene = butadiene or cyclohexadiene);  $\nu(\text{CO})$  (1,1-isomer) 2091m, 2040s, 2012sh, 2005vs, 1987sh, 1980w, 1957m, 1913sh, 1908w cm<sup>-1</sup> (cyclohexane solution) [12].

(c)  $[\text{HOs}_3(\text{CH=CH-n-Bu})(\text{CO})_{10}]$ . Addition of  $\text{PMe}_2\text{Ph}$  (0.030 cm<sup>3</sup>) to the  $\text{CH=CH-n-Bu}$  complex (0.050 g) in acetone (30 cm<sup>3</sup>) gave the adduct at  $-70^\circ\text{C}$  (infrared evidence). After warming to room temperature, TLC separation after 5 h gave starting complex (0.005 g) and  $[\text{1,2-Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$  (0.002 g) as the only isolable products.

(d)  $[\text{HOs}_3(\text{CPh=CHPh})(\text{CO})_{10}]$ .  $\text{PMe}_2\text{Ph}$  (0.010 cm<sup>3</sup>) was added to the  $\text{CPh=CHPh}$  compound (0.023 g) in ethanol (10 cm<sup>3</sup>). After 24 h at room temperature, TLC separation gave two isomers of  $[\text{Os}_3(\text{CO})_{10}(\text{PMe}_2\text{Ph})_2]$ , 1,1-isomer (0.001 g) and the 1,2-isomer (0.016 g).

*Preparation of  $[N(PPh_3)_2][Os_3H(CHCH_2CN)(CO)_{10}]$*

A mixture of potassium cyanide (0.030 g),  $[Os_3H(CH=CH_2)(CO)_{10}]$  (0.347 g) and  $[N(PPh_3)_2]Cl$  (excess) in ethanol (170 cm<sup>3</sup>) was heated for 5 min on a steam bath. Most of the solvent was removed under vacuum and diethyl ether (50 cm<sup>3</sup>) was added to precipitate the excess of  $[N(PPh_3)_2]Cl$ , which was then filtered off. The yellow ether solution was washed with water and dried over  $MgSO_4$ . Evaporation to dryness gave orange crystals of the product (0.480 g, 84%) (Found: C, 41.5; H, 2.5; N, 1.9.  $C_{49}H_{34}N_2O_{10}Os_3P_2$  calcd.: C, 40.8; H, 2.4; N, 1.9%). Similar treatments of  $[Os_3H(CHCHPh)(CO)_{10}]$  and  $[Os_3H(CHCH-n-Bu)(CO)_{10}]$  also gave the complexes  $[N(PPh_3)_2][Os_3H(CHCHRCN)(CO)_{10}]$  (R = Ph or n-Bu) as yellow or orange solids which were characterised by infrared ( $\nu(CN)$  2220 cm<sup>-1</sup>) and NMR spectroscopy (see Tables) but which were not obtained analytically pure.

*Preparation of  $[N(PPh_3)_2][Os_3H(CHCH_2OMe)(CO)_{10}]$*

A solution of  $[N(PPh_3)_2]Cl$  (0.17 g), sodium methoxide (0.010 g), and  $[Os_3H(CH=CH_2)(CO)_{10}]$  (0.078 g) in methanol (20 cm<sup>3</sup>) was allowed to stand for 30 min before evaporation to dryness under vacuum. Extraction with  $CH_2Cl_2$  (2 cm<sup>3</sup>) and addition of diethyl ether (30 cm<sup>3</sup>) gave a precipitate of  $[N(PPh_3)_2]Cl$  which was filtered off. Evaporation gave the product as a yellow oil (analytically impure) which was characterised by its spectra (see Tables).

*Reaction of  $[HOs_3(CH=CH_2)(CO)_{10}]$  with diethylamine and methanolic sodium methoxide*

Diethylamine (1 cm<sup>3</sup>), sodium methoxide (0.010 g) and the vinyl cluster (0.100 g) were dissolved in methanol (40 cm<sup>3</sup>) and heated under reflux for 3 h under nitrogen. Removal of solvent and TLC separation gave  $[HOs_3(OMe)(CO)_{10}]$  (0.022 g, 22%),  $[HOs_3(CHCH=NEt_2)(CO)_{10}]$  (0.005 g, 5%), and  $[HOs_3(OH)(CO)_{10}]$  (0.015 g, 15%), all characterised by comparison of their spectra with those of authentic samples.

*Protonation reactions*

*Reaction of  $[N(PPh_3)_2][HOs_3(CHCH_2CN)(CO)_{10}]$  with hydrogen chloride.* HCl gas was bubbled through a solution of the complex (0.043 g) in  $CDCl_3$  (0.5 cm<sup>3</sup>) in an NMR tube. The <sup>1</sup>H NMR spectrum showed the quantitative formation of  $[HOs_3Cl(CO)_{10}]$  and  $CH_3CH_2CN$ , both characterised by comparison of spectra with those of authentic samples. A similar treatment of  $[N(PPh_3)_2][HOs_3(CHCH_2OMe)(CO)_{10}]$  but with trifluoroacetic acid gave  $[HOs_3(CH=CH_2)(CO)_{10}]$  quantitatively.

*Reaction of  $[HOs_3(CHCH_2PMe_2Ph)(CO)_{10}]$  with hydrogen chloride.* HCl gas was bubbled through a solution of the cluster (0.046 g) in chloroform. The <sup>1</sup>H NMR spectrum showed only  $[HOs_3Cl(CO)_{10}]$  and  $[EtPMe_2Ph]^+$  as products. The cluster was isolated after chromatography (0.034 g, 85%) as orange crystals.

**Acknowledgements**

We thank the SERC for a research studentship and Johnson-Matthey Ltd for a generous loan of osmium tetroxide.
