### Summary

UV irradiation of  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)_2]$  yields the tri- and tetra-ruthenium complexes  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)\{\eta\text{-C}_5\text{H}_4\text{Ru}(\text{CO})_2(\eta\text{-C}_5\text{H}_5)\}]$  and  $[\text{Ru}_4(\text{CO})_6(\mu_3\text{-C}_5\text{H}_4)_2(\eta\text{-C}_5\text{H}_5)_2]$ . The  $\mu_3\text{-C}_5\text{H}_4$  ligand in the latter has been characterised through an X-ray diffraction study on  $[\text{Ru}_4(\text{CO})_5\{\text{P}(\text{OMe})_3\}(\mu_3\text{-C}_5\text{H}_4)_2(\eta\text{-C}_5\text{H}_5)_2]$ .

It has been established that upon UV irradiation dimeric  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)_2]$  undergoes Ru—Ru bond fission to generate  $\text{Ru}(\text{CO})_2(\eta\text{-C}_5\text{H}_5)$  radicals [1]. We now report that these radicals attack cyclopentadienyl rings and that after extended irradiation the major product is a tetra-ruthenium complex containing the cyclopentadienylidene ligand, observed for the first time bridging three transition metal atoms.

UV irradiation (250 W mercury lamp, silica flask) of  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)_2]$  in toluene solution for 3 d gives  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)\{\eta\text{-C}_5\text{H}_4\text{Ru}(\text{CO})_2(\eta\text{-C}_5\text{H}_5)\}]$  (I) (4%) and  $[\text{Ru}_4(\text{CO})_6(\mu_3\text{-C}_5\text{H}_4)_2(\eta\text{-C}_5\text{H}_5)_2]$  (IIa) (45%).

The former, which has been previously described [2] as a side-product of the photochemical reaction of  $[\text{Ru}_2(\text{CO})_4(\eta\text{-C}_5\text{H}_5)_2]$  with diphenylacetylene, clearly results from  $\text{Ru}(\text{CO})_2(\eta\text{-C}_5\text{H}_5)$  radical attack upon one cyclopentadienyl ring of the diruthenium compound. Further attack on the second ring would lead to the unobserved complex (III) which, through loss of two CO ligands and Ru—Ru bond formation as indicated, can be seen as the precursor of the isolated product (IIa). This yellow, air-stable complex gave no crystals suitable for an X-ray diffraction study, but on treatment with trimethylphosphite under UV irradiation an orange mono-substituted derivative (IIb) was obtained which did yield such a crystal.

**Crystal data:** C<sub>28</sub>H<sub>27</sub>O<sub>8</sub>PRu<sub>4</sub>, *M* = 927, triclinic, space group  $P\bar{1}$ , *a* 12.557(4), *b* 15.818(4), *c* 8.294(2) Å,  $\alpha$  104.70(2),  $\beta$  103.60(2),  $\gamma$  105.95(2)°, *U* 1447.5(6) Å<sup>3</sup>, *Z* = 2, *D*<sub>x</sub> 2.13 g cm<sup>-3</sup>, *F*(000) = 900, Mo-*K*<sub>α</sub> X-radiation,  $\lambda$  0.710 69 Å,  $\mu$ (Mo-*K*<sub>α</sub>) 21.1 cm<sup>-1</sup>; *R* = 0.063 for 4678 unique, observed (*I* > 2σ(*I*)) absorption-corrected diffracted intensities, measured for 4 < 2θ < 55° at 295 K on a Nicolet P3m diffractometer.

The molecular geometry of IIb is illustrated in Fig. 1. The molecule has an Ru<sub>4</sub> chain which can be considered as two Ru<sub>2</sub> units joined by the central Ru(2)—Ru(3) bond, the longest of the three Ru—Ru bonds. The Ru(1)—Ru(2) and Ru(3)—Ru(4) bonds are bridged by carbonyl ligands, and each Ru atom carries a terminal CO or P(OMe)<sub>3</sub> ligand (Ru(1) only). The terminal Ru atoms each bear a conventional η<sup>5</sup>-C<sub>5</sub>H<sub>5</sub> ligand, but the other C<sub>5</sub> rings bind in a most unusual manner, bridging three ruthenium atoms η<sup>5</sup> to one and η<sup>1</sup> to each of the other two. Cyclopentadienylidene has been observed bound to AlTi<sub>2</sub> [3], Al<sub>2</sub>Mo [4] and FeAu<sub>2</sub> [5] units, but not to three transition metal atoms. The triply-bridging carbons C(21) and C(31) show highly asymmetric Ru—C distances (see caption of Fig. 1) being more closely linked to the terminal atoms of the Ru<sub>4</sub> chain, and are also displaced out of the plane of their C<sub>5</sub> rings (by 0.11 and 0.06 Å, respectively) towards these atoms. The bonding of the C<sub>5</sub>H<sub>4</sub> ligands is evidently highly delocalised and not satisfactorily described by any single Valence Bond representation, but that shown as IV clearly contributes significantly.

The ligands are disposed about the Ru(3)Ru(4) unit so that the terminal carbonyls are *trans*, and about Ru(1)Ru(2) so that the terminal CO and P(OMe)<sub>3</sub> ligands are *cis* to one another. If the same *cis*—*trans* situation arose in IIa then the η-C<sub>5</sub>H<sub>5</sub> ligands would be inequivalent, and this is indeed the case, two signals of equal intensity being observed at δ 5.01 and 5.42 ppm

Fig. 1. Molecular structure of IIb. Selected bond lengths (Å): Ru(1)—Ru(2) 2.755(1), Ru(2)—Ru(3) 2.887(1), Ru(3)—Ru(4) 2.767(1), Ru(1)—P(1) 2.217(3), Ru(1)—C(21) 2.119(7), Ru(2)—C(21) 2.281(10), Ru(3)—C(21) 2.386(8), Ru(3)—C(22) 2.207(10), Ru(3)—C(23) 2.196(12), Ru(3)—C(24) 2.242(13), Ru(3)—C(25) 2.251(9), Ru(2)—C(31) 2.320(11), Ru(3)—C(31) 2.331(10), Ru(4)—C(31) 2.117(10). Bond angles ( $^{\circ}$ ): Ru(1)—Ru(2)—Ru(3) 101.7(1), Ru(2)—Ru(3)—Ru(4) 99.6(1), Ru(1)—C(21)—Ru(2) 77.4(3), Ru(2)—C(21)—Ru(3) 76.4(3), Ru(2)—C(31)—Ru(3) 76.8(3), Ru(3)—C(31)—Ru(4) 76.8(3).

in the  $^1\text{H}$  NMR spectrum. However, another isomer is present in greater amount (ca. 2.5/1 in  $\text{CDCl}_3$  at  $30^{\circ}\text{C}$ ), and this displays a single  $\eta\text{-C}_5\text{H}_5$  resonance at  $\delta$  5.41 ppm, as expected when both  $\text{Ru}_2$  units have the same stereochemistry. This is so for either the *cis-cis* or the *trans-trans* isomer, but inspection of a molecular model indicates that on steric grounds the *trans-trans* form is the most favoured of the three possible isomers, and it therefore appears likely that it is this species which is also present in solution. For the *trans-trans* symmetrical isomer the  $^1\text{H}$  NMR spectrum shows the  $\mu_3\text{-C}_5\text{H}_4$  signals as multiplets at  $\delta$  2.42 (2 H), 4.92 (2 H), 5.19 (2 H), and 5.97 (2 H) ppm, while the  $^{13}\text{C}$  NMR spectrum reveals alkylidene character in the  $\mu_3$ -carbon, emphasised by the representation IV, in its low field shift of 122.1 ppm.

The isomers of IIa may be partially separated by chromatography, but interconvert slowly on heating such that at 60°C in pyridine-*d*<sub>5</sub> the *trans-trans/cis-trans* ratio is reversed to reach ca. 1/2. In accord with an earlier study [6] of the *cis*⇌*trans* isomerisation of  $\mu$ -alkylidene complexes  $[\text{Ru}_2(\text{CO})_2(\mu\text{-CO})(\mu\text{-CR}_2)(\eta\text{-C}_5\text{H}_5)_2]$ , the interconversion of the isomers of IIa requires that the  $\mu\text{-CO}$  and  $\mu_3\text{-C}_5\text{H}_4$  ligands temporarily adopt the situation shown in V, thereby allowing rotation about an exterior Ru—Ru bond to exchange the terminal CO and  $\eta\text{-C}_5\text{H}_5$  environments. Such bridging of a dimetal centre by  $\text{C}_5\text{H}_4$  has been observed [7].

Complex IIa does not convert to III even under 50 atm of CO at 125°C, but reacts with hydrogen under UV irradiation to yield  $[\text{Ru}_3(\text{CO})_3(\mu\text{-H})_3(\eta\text{-C}_5\text{H}_5)_3]$  (18%) [8]. Ruthenium—ruthenium bonds in IIa are cleaved by iodine in chloroform to afford  $[\text{RuI}(\text{CO})_2\{\eta\text{-C}_5\text{H}_4\text{Ru}(\text{CO})_2(\eta\text{-C}_5\text{H}_5)\}]$  VI in good yield.

We are grateful to the S.E.R.C. for the award of Research Studentships (N.D.F., N.J.F., G.H., K.A.M., and M.J.M.) and for support, and to Johnson Matthey for a loan of ruthenium trichloride.
