$\pi/\sigma$  Equilibria in rhenium ketone complexes  
 $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\text{O}=\text{CRR}')]^+\text{X}^-$ ;  
 a marked electronic effect upon the binding mode

**Abstract**

The first series of metal ketone complexes for which both  $\sigma$  and  $\pi$  isomers can be isolated is reported. Electron-withdrawing substituents favor the  $\pi$  binding mode.

Although many examples of  $\pi$  and  $\sigma$  ketone complexes have been reported [1], there have been few systematic studies of the factors that influence the binding mode. In previous work, Taube and Harman have shown that the  $\pi$  isomer of the osmium acetone complex  $[\text{Os}(\text{NH}_3)_5(\text{O}=\text{C}(\text{CH}_3)_2)]^{2+}$  is  $> 16$  kcal/mol more stable than the  $\sigma$  isomer [2]. However, upon one-electron oxidation, which reduces metal  $\pi$  basicity, the  $\sigma$  isomer is favored by 5 kcal/mol. We wondered whether an analogous ligand-based electronic effect upon  $\pi/\sigma$  equilibria might be possible. For example, rhenium methyl ketone complexes of the formula  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\eta^1\text{-O}=\text{C}(\text{CH}_3)\text{R})]^+\text{X}^-$  ( $\text{R} = \text{CH}_3, \text{CH}_2\text{CH}_3, \text{CH}(\text{CH}_3)_2, \text{C}(\text{CH}_3)_3, \text{C}_6\text{H}_5$ ) exist as  $\sigma$  isomers ( $> 97:3 \sigma/\pi$ ) [3]. However, the corresponding aliphatic aldehyde complexes exhibit only  $\pi$  binding modes [4]. Hence, we sought to synthesize rhenium complexes of ketones with electron-withdrawing substituents [5\*]. Such ligands should be stronger  $\pi$  acids, and thus more likely to exhibit a  $\pi$  binding mode.

Reaction of the substitution-labile dichloromethane complex  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\text{ClCH}_2\text{Cl})]^+\text{BF}_4^-$  (1) [3] and excess 1,3-dichloroacetone was monitored by  $^1\text{H}$  and  $^{31}\text{P}$  NMR at  $-36^\circ\text{C}$  (eq. i). A product formed in high yield ( $2^+\text{BF}_4^-$ ), but decomposed upon attempted workup. However, spectroscopic properties ( $^{31}\text{P}$  NMR 9.4 ppm, IR  $\nu(\text{NO})$  1745–1740  $\text{cm}^{-1}$ ) resembled those found earlier for  $\pi$  aldehyde complexes [4,6], and differed from those of  $\sigma$  ketone complexes ( $^{31}\text{P}$  NMR 18–19

\* Reference number with asterisk indicates a note in the list of references.

ppm, IR  $\nu(\text{NO})$  1697–1680  $\text{cm}^{-1}$ ) [3]. Thus, 2<sup>+</sup>BF<sub>4</sub><sup>-</sup> was tentatively assigned as the  $\pi$  ketone complex  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\eta^2\text{-O}=\text{C}(\text{CH}_2\text{Cl})_2)]^+\text{BF}_4^-$ .

Next, **1** and 1,3-difluoroacetone were similarly allowed to react in  $\text{CH}_2\text{Cl}_2$  at  $-80^\circ\text{C}$ . Subsequent addition of ether (room temperature) precipitated the product  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\eta^2\text{-O}=\text{C}(\text{CH}_2\text{F})_2)]^+\text{BF}_4^-$  (3<sup>+</sup>BF<sub>4</sub><sup>-</sup>, 71%), which was assigned as a  $\pi$  ketone complex as described below. Alternatively, reaction of hydride complex  $(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\text{H})$ ,  $\text{Ph}_3\text{C}^+\text{PF}_6^-$ , and 1,3-difluoroacetone ( $\text{CH}_2\text{Cl}_2$ ,  $-80^\circ\text{C}$ ) gave analytically pure 3<sup>+</sup>PF<sub>6</sub><sup>-</sup> (66%) [7\*]. This synthesis is analogous to one recently reported for the corresponding cationic alcohol complexes [8].

IR spectra of 3<sup>+</sup>X<sup>-</sup> ( $\nu(\text{NO})$  1762–1749  $\text{cm}^{-1}$ ) showed no traces of any absorptions in regions characteristic of  $\sigma$  complexes [3,6]. The <sup>13</sup>C NMR spectrum of 3<sup>+</sup>PF<sub>6</sub><sup>-</sup> exhibited an upfield CO resonance (83.5 ppm) that was coupled to both fluorines ( $\sigma$  ketone complexes [3]: 216–240 ppm), and two CH<sub>2</sub>F resonances. Two CH<sub>2</sub>F <sup>19</sup>F NMR resonances were also observed ( $\Delta\nu$  2536 Hz, 282.7 MHz). These did not coalesce at  $50^\circ\text{C}$ , which sets a lower limit of 13.4 kcal/mol on any dynamic process capable of exchanging the CH<sub>2</sub>F groups (e.g.,  $\pi \rightarrow \sigma \rightarrow \pi'$  isomerization) [3].

Yellow plates of 3<sup>+</sup>PF<sub>6</sub><sup>-</sup> were grown from  $\text{CH}_2\text{Cl}_2/\text{ether}$ , and the structure was confirmed by X-ray crystallography (Fig. 1) [9\*]. The 1,3-difluoroacetone ligand adopts a conformation that maximizes overlap of the  $\text{C}=\text{O}$   $\pi^*$  acceptor orbital with the rhenium fragment HOMO I (angle between Re–O–C plane and Re–P bond:  $10^\circ$ ). Similar solid state conformations are found with analogous  $\pi$  aldehyde complexes [4,6a]. The  $\alpha$  carbons C25 and C26 are displaced 0.62 Å and 0.34 Å, respectively, from the nodal plane of the free ligand. Also, the  $\text{C}\equiv\text{O}$  bond (1.35(1) Å) is much longer than that in the  $\sigma$  acetone complex  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\eta^1\text{-O}=\text{C}(\text{CH}_3)_2)]^+\text{PF}_6^-$  (1.248(9) Å) [3].

Other halogenated ketones were briefly studied. An analogous reaction of **1** and pentafluoroacetone gave the analytically pure adduct  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\text{O}=\text{C}(\text{CH}_3)\text{C}_6\text{F}_5)]^+\text{BF}_4^-$  (4<sup>+</sup>BF<sub>4</sub><sup>-</sup>; 55%) [10\*]. The NMR properties of 4<sup>+</sup>BF<sub>4</sub><sup>-</sup> in  $\text{CD}_3\text{NO}_2$  at  $-30^\circ\text{C}$  were consistent with those expected for a  $\pi$

Fig. 1. Views of the cation of difluoroacetone complex  $[(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{NO})(\text{PPh}_3)(\eta^2\text{-O}=\text{C}(\text{CH}_2\text{F})_2)]^+\text{-PF}_6^-$  ( $3^+ \text{PF}_6^-$ ): (a) numbering diagram; (b) view down rhenium–nitrogen bond with phenyl groups omitted. Selected bond lengths (Å) and angles ( $^\circ$ ): Re–C24 2.17(1), Re–O2 2.044(6), C24–O2 1.35(1), Re–N 1.737(9), Re–P 2.449(3), N–O1 1.19(1); O2–Re–C24 37.1(3), Re–O2–C24 76.5(5), Re–C24–O2 66.4(5), Re–N–O1 173(1), N–Re–P 90.5(3).

complex [10]. However, IR spectra at room temperature showed minor, medium-dependent amounts of a  $\sigma$  isomer ( $\nu(\text{NO})$ ,  $\text{cm}^{-1}$ :  $\pi$  1745–1749,  $\sigma$  1699–1695  $\text{cm}^{-1}$ ;  $\text{CH}_3\text{NO}_2$  ca. 75 : 25,  $\text{CH}_2\text{Cl}_2$  and KBr ca. 56 : 44). Similar solvent and temperature trends have been observed for related equilibria [6]. Fluoroacetone gave a less stable complex that appeared by  $^{31}\text{P}$  NMR ( $\text{CH}_2\text{Cl}_2$ ,  $-80^\circ\text{C}$ : 8.8, 18.0 ppm) to be a mixture of  $\pi$  and  $\sigma$  isomers.

In summary, this study has provided the first examples of  $\pi$  and  $\sigma$  ketone complexes of the same metal fragment, and established a marked ligand-based electronic effect upon the binding mode. Complementary trends have recently been documented with analogous aromatic aldehyde complexes [6]. Future efforts will be directed at quantifying  $\pi/\sigma$  isomer interconversion rates, and differences in chemical reactivity.
