The products of the reaction of laser-ablated red phosphorus and dioxygen have been studied using experiment and theory. The bands at 480.3 and 1273.3 cm^{-1} , previously attributed to PO_3 in the matrix isolation IR experiments, are reassigned to PO_3^- . Also observed in experiment are PO_2 , PO_2^- , P_2O , OPOPO , P_4 , and higher oxides.

I. Introduction

In 1988 Withnall and Andrews¹ reported the infrared (IR) spectra arising from the products of the reaction of PH_3 with atomic oxygen trapped in solid argon. They attributed bands at 480.3 and 1273.3 cm^{-1} to the a_2'' out-of-plane bend and e' P–O stretching modes of PO_3 , respectively. They also tentatively assigned a band at 435.2 cm^{-1} as the e' bending mode of the same molecule. The assignment was based in large part on the spectra with mixed $^{16,18}\text{O}$, which clearly showed that the a_2'' mode arose from a species with three equivalent oxygen atoms, and on the fact that using PD_3 , instead of PH_3 , showed that the species did not include any hydrogen.

In 1989 Withnall, McCluskey, and Andrews² reported the electronic spectra of the species previously assigned as PO_3 . They observed a band system starting at 695.5 nm with progressions of about 900 and 525 cm^{-1} . On the basis of comparison with NO_3 and SO_3^+ , they assigned the observed transition as ${}^2E' \leftarrow X^2A_2'$, the $913 \pm 10 \text{ cm}^{-1}$ interval to the a_1' symmetric stretch in the ground state, and the 525 cm^{-1} interval to the excited state.

As part of our recent study³ of the heats of formation of PO_n and PO_nH , $n = 1-3$, we computed the vibrational frequencies of these species. The computed frequencies of all of the molecules, except PO_3 , agreed with experiment. Because we expected similar accuracy for all of the species, we looked for an alternative assignment of the experimental IR bands. We found that the computed a_2'' out-of-plane bend and the e' stretch of PO_3^- agreed much better with the experiment than did the computed PO_3 results. Unfortunately, the computed results for neither molecule agreed well with the 435.2 cm^{-1} band.

In this paper we report on the electronic spectra and on higher level calculations for the IR spectra of PO_3 and PO_3^- . New experiments are also performed to test the PO_3^- hypotheses. Other bands are observed in these experiments, so additional calculations are performed for P_nO_m species to aid in the identification of the observed bands. We should note that many of the P_nO_m species have been studied by Lohr and co-workers⁴ at the Hartree–Fock level. In this work, we use a higher level of theory which results in more accurate frequencies; we also

consider the effect of isotopic substitution, and consider some species not considered previously.

II. Computational Methods

The geometries are optimized and the harmonic frequencies computed using the hybrid⁵ B3LYP⁶ functional in conjunction with the 6-31+G* and 6-31+G(2df) basis sets.⁷ The vertical electronic excitation energies are computed using the time-dependent B3LYP approach⁸ with the 6-31+G(d) basis set. The harmonic frequencies are also determined using the coupled cluster singles and doubles approach⁹ including the effect of connected triples determined using perturbation theory,¹⁰ CCSD(T). All electrons are correlated in the CCSD(T) calculations. The open-shell calculations are based on unrestricted Hartree–Fock (UHF) wave functions. The 6-31G* and 6-31+G(2df) basis sets are used in conjunction with the CCSD(T) calculations.

The harmonic frequencies are computed using both ^{16}O and ^{18}O . Errors in the computed values prevent a definitive identification of the experimental bands using only the ^{16}O computed frequencies. However, for each band, the ratio of the frequencies determined using ^{16}O to the frequencies determined using ^{18}O , denoted $R(16/18)$, is also computed. This ratio is more accurate than the frequencies and therefore is very helpful in identifying the bands.

The B3LYP calculations are performed using Gaussian 98,¹¹ while the CCSD(T) calculations are performed using ACES II.¹² The B3LYP/6-31+G* geometries are given at <http://ccf.arc.nasa.gov/~cbauschl/p2o5.geometry>.

III. Experimental Methods

The experiment for laser ablation and matrix isolation has been described in detail previously.¹³ Briefly, the Nd:YAG laser fundamental (1064 nm, 10 Hz repetition rate with 1–5 mJ pulses of 10 ns width) was focused on a rotating red phosphorus (Aldrich, lump) target. Laser-ablated phosphorus was codeposited with oxygen (1%) in excess argon onto a 10 K CsI cryogenic window at 2 mmol/h for 1 h. FTIR spectra were recorded at 0.5 cm^{-1} resolution on a Nicolet 750 spectrometer with 0.1 cm^{-1} accuracy using a HgCdTe detector. Matrix samples were annealed at different temperatures and subjected

IV. Results and Discussion

We first consider the computational study of PO₃ and PO₃⁻, which is summarized in Tables 1–3. We then describe the new experimental work; these results are summarized in Table 4. The additional calculations performed to support the experimental study are summarized in Tables 5–12.

The ground state of PO₃ is ²A₂['], which has *D*_{3h} symmetry. PO₃⁻ is a closed shell and also has *D*_{3h} symmetry. The two species have very similar bond lengths; for example, at the CCSD(T)/6-31+G(2df) level, the P–O bond length in PO₃⁻ is 1.492 Å compared with 1.482 Å for PO₃. At this level of theory, the electron affinity of PO₃ is 4.99 eV, which is similar to the value of 4.77 eV found at the B3LYP/6-31+G(2df) level.

The computed PO₃ and PO₃⁻ harmonic frequencies and intensities are summarized in Tables 1 and 2. Excluding the e' bending mode of PO₃, all of the results are fairly independent of the level of theory used. The experimental bands at 480.3 and 1273.3 cm⁻¹ with ¹⁶O to ¹⁸O isotopic ratios ($R(16/18)$) of 1.0219 and 1.0314, respectively, agree better with the computed results for PO₃⁻ than for PO₃. This is especially true for the

TABLE 3: Summary of the Vertical Excitation Energies (eV) and *f* Values of PO₃ and PO₃⁻

PO ₃			PO ₃ ⁻		
state	Δ	<i>f</i>	state	Δ	<i>f</i>
² E''	1.30	0.0000	¹ A ₂ '	4.42	0.0000
² E'	1.96	0.0014	¹ E''	5.62	0.0000
² E'	4.21	0.0040	¹ A ₂ '	5.65	0.0000
² A ₁ '	4.23	0.0000	¹ E'	6.23	0.0128

1273.3 cm⁻¹ band, where the computed PO₃ value differs by more than 100 cm⁻¹ with experiment, while the value for PO₃⁻ differs by much less. The experimental band at 435.2 cm⁻¹ with an isotopic ratio of 1.0340 does not correspond very well with either PO₃ or PO₃⁻.

The in-plane O 2p orbitals perpendicular to the P–O bonds form a₂' and e' orbitals. The a₂' orbital is singly occupied in neutral PO₃, but doubly occupied in the anion. The one fewer electron should reduce the O–O repulsion in the neutral and may be responsible for the lower in-plane e' bending frequency for PO₃ than for PO₃⁻.

The electronic spectra of PO₃ and PO₃⁻ are computed using the time-dependent B3LYP approach using the 6-31+G(d) basis set at the PO₃ B3LYP/6-31+G(2df) geometry, and the results are summarized in Table 3. For PO₃⁻, the first transition is at 4.42 eV, and the first allowed transition is at 6.23 eV. For PO₃, the computed transitions lie at 1.30, 1.96, 4.21, and 4.23 eV, with the transitions at 1.96 and 4.21 eV being allowed. The allowed transition at 1.96 eV agrees with the experimental value of 1.78 eV to within the expected uncertainty (± 0.3 eV) of the theoretical method used. Since there are no other allowed transitions in this region, we agree with Withnall, McCluskey, and Andrews that the band they observe in experiment arises from PO₃ and should be assigned as ²E' ← X²A₂'. The current results show that the progression at 525 cm⁻¹ should be attributed to the upper state as done by Withnall, McCluskey, and Andrews. It is more difficult to assign the progression at about 900 cm⁻¹; the experimental value is similar to that of the a₁' mode of the PO₃ ground state, as suggested by Withnall, McCluskey, and Andrews, but the difference between theory and experiment is larger than expected. Given the size of the difference between theory and experiment for the vibrational frequency and the matrix temperature (12 K), we would be more tempted to assign this to the upper state than to the ground state.

While the assignment of the 480.3 and 1273.3 cm⁻¹ bands to PO₃⁻ seems straightforward, it is disconcerting that the e' bending mode of PO₃⁻, which has about the same intensity as the a₂'' mode, cannot be assigned to any of the observed bands. Also, given that the electronic spectra clearly show the existence of PO₃, it is disconcerting that e' P–O stretching and a₂'' out-of-plane bending modes of PO₃ have not been observed.

Early experiments employed laser-ablated red phosphorus as a reagent for dioxygen diluted in argon.¹⁴ Similar experiments were done using lower oxygen concentration, lower laser power, and a rotating red phosphorus target to minimize the amount of ablated phosphorus and to favor the ablation of P atoms. Representative spectra are shown in Figures 1–3, and the absorptions are listed in Table 4; the related theoretical data are presented in Tables 5–12.

The strong sharp 1319.0 cm⁻¹ absorption has been assigned to the antisymmetric stretching fundamental (ν_3) of PO₂ in solid argon.^{1,14–18} This absorption is red-shifted 8.5 cm⁻¹ from the gas-phase¹⁹ diode laser value of 1327.53 cm⁻¹. The reaction with ¹⁸O₂ displaces the 1319.0 cm⁻¹ absorption to 1280.0 cm⁻¹. The associated bending mode was observed at 386.8 cm⁻¹ in other experiments using a grating instrument. Both infrared

active modes of PO_2 are in satisfactory agreement with our B3LYP calculations; compare the results in Tables 4 and 5.

The next strongest absorption at 1198.6 cm^{-1} has been assigned to the PO_2^- anion;^{14,16} the $^{18}\text{O}_2$ counterpart appears at 1160.6 cm^{-1} . Our yield is not sufficient to observe the bending mode reported at 470 cm^{-1} in the gas phase.²⁰ New experiments were performed to investigate the effect of a CCl_4 electron trap^{21–24} on the relative yields of PO_2 and PO_2^- . Figure 2 shows that CCl_4 doping reduces the absorptions of PO_2 to 50%, of PO_2^- to 40%, of P^{18}O_2 to 57%, and of $\text{P}^{18}\text{O}_2^-$ to 27% of their values without CCl_4 . (Part of the overall reduction may be due to a lower yield of P atoms as P_4 was reduced to 65% in the 0.2% CCl_4 doped 1% O_2 experiment; this probably arises from ablation out of the groove on the target used in the previous experiment.) Annealing to 25 K reduced PO_2 by 20% and the PO_2^- band by 50%. Annealing to 30–40 K further decreased PO_2 and markedly increased O_2PPO_2 absorptions (Table 4). In addition, weak CCl_3 radical, CCl_3^+ cation, and $\text{Cl}-\text{CCl}_3$ transient absorptions were observed.^{25–28}

The effect of added CCl_4 is to compete with PO_2 for ablated electrons and reduce the yield of anions relative to neutral molecules. In transition metal carbonyl systems, doping with 10% as much CCl_4 as CO present essentially eliminates the transition metal carbonyl anions from the spectrum. However, with NO and NO_2 , CCl_4 doping reduced NO_2^- to 50% and $(\text{NO}_2)^-$ bands to 30% of the yields without CCl_4 added.²⁹ Clearly, NO_2 and PO_2 are good electron traps themselves, and

they do not give in to CCl_4 as readily as transition metal carbonyls. Nevertheless, the decrease of PO_2^- absorptions relative to PO_2 bands is sufficient to confirm the PO_2^- anion assignment.

Figure 3 shows the lower region containing the PO_3^q , O_2PPO_2 , and P_4 absorptions at 480.2, 479.4, and 465.8 cm^{-1} , respectively, in the 1% O_2 experiment.^{1,15,16} The 480.2 cm^{-1} absorption was particularly noteworthy as it gave the 1/3/3/1 quartet with statistical $^{16,18}\text{O}_2$ characteristic of the nondegenerate motion of three equivalent oxygen atoms.¹ Doping with 0.2% CCl_4 reduced these band absorbances to 38%, 60%, and 65% of yields in the experiment without CCl_4 . Annealing to 25 K slightly decreased the PO_3^q band, tripled the O_2PPO_2 , band, and increased the P_4 absorption by 8%. The effect of added CCl_4 is to reduce the PO_3^q absorption at 480.2 cm^{-1} sufficiently to conclude that $q = -1$. Reassignment of the 480.2 cm^{-1} band to PO_3^- is indicated by the present calculations and experiments.

We do not observe any band that we can assign as the e'

in-plane bending mode of PO₃⁻, which is computed to be a strong transition and have a frequency very similar to that of the a₂'' band. The question naturally arises of whether the a₂'' and e' bands are strongly overlapped. While the band at 480.2 cm⁻¹ is definitely two overlapped bands, one grows on annealing and the other is the photosensitive band that we assign to PO₃⁻. Given their different behaviors, it is difficult to assign these two components of the 480.2 cm⁻¹ band to the same molecule. Thus, we see no evidence supporting the idea that the a₂'' and e' bands are strongly overlapped.

The band at 1218.0 cm⁻¹ is due to PO, and the B3LYP results are in good agreement; see Tables 4 and 5. The band at 1270.3 cm⁻¹ with an isotopic ratio of 1.0293 is in very good agreement with the B3LYP results (1266 cm⁻¹ and 1.0310) for the P–O stretch in the linear PPO species, which is also computed to have a large intensity; see Table 6.

We do not see any indication of P₂O₂ (planar with D_{2h} symmetry), which is computed to have a strong band at 724 cm⁻¹; see Table 6. However, the bands at 1253.4, 1247.8, and 859.3 cm⁻¹ should be assigned, as previously suggested,³⁰ to the O=P–O–P=O isomer of P₂O₃, which is the most stable of the P₂O₃ isomers studied; compare the results in Tables 4 and 7. We do not see any evidence for the higher energy O₂-PPO isomer.

In previous P₂ oxidation experiments from this laboratory,^{16,18} bands at 1438.4, 1168.1, and 955.4 cm⁻¹ (labeled Y in the

^a The relevant experimental bands from Table 4 are given in parentheses for comparison.

previous work) were assigned to oxo-bridged P₂O₄ (i.e., O₂P–O–PO). These bands are not observed in the present experiments, but the strongest calculated bands (Table 8) are compatible with this assignment. The earlier studies^{16,18} also produced a species X (see Figure 1) absorbing at 1450.0 and 1007.9 cm⁻¹, which was attributed to structural isomers of oxo-bridged P₂O₄; these bands are observed here at 1449.5 and 1007.5 cm⁻¹, and they increase markedly on annealing (Figure 1).

Sharp absorptions observed here at 1473.2, 1158.2, 735.1, and 479.4 cm⁻¹ (labeled ↓) increased markedly (×4) on annealing to 25 K. These bands were assigned to P₂O₅ after formation in six different phosphorus/oxygen experiments.^{14–18} The most important diagnostic evidence is the triplet of triplets first reported for the 1158.1 cm⁻¹ band using statistical isotopic oxygen.¹ This clearly indicates two equivalent PO₂ groups each with equivalent oxygen atoms. Furthermore, the 1473.2 and 1158.1 cm⁻¹ bands show 16/18 isotopic ratios for antisymmetric and symmetric P–O stretching modes in a phosphoryl subgroup. The current P₂O₅ B3LYP calculations (see Table 9) and the older HF/6-21G* calculations of Lohr⁴ find a C₂ structure with inequivalent O atoms and a splitting in the strong antisymmetric O–P–O stretching mode. Furthermore, both calculations predict the strongest band, the antisymmetric P–O–P stretching mode, in the 900–1000 cm⁻¹ region; no such band is observed in the spectrum. Therefore, the calculations cast doubt on the earlier P₂O₅ assignment.

The next best possibility is O₂PPO₂, the D_{2d} form of symmetrical P₂O₄. The strongest band (e) calculated at 1432 cm⁻¹ with a 1.0309 16/18 ratio is appropriate for the antisymmetric PO₂ mode and the 1106 cm⁻¹ band for the out-of-phase symmetric PO₂ mode. The computed 16/18 ratios are in good agreement with those determined experimentally. Scale factors

^a The relevant experimental bands from Table 4 are given in parentheses for comparison.

that bring the B3LYP frequencies for these two modes into agreement with experiment, 1.029 and 1.047, are comparable. The computed band at 422 cm⁻¹ is consistent with the experimental band at 479.4 cm⁻¹, but the differences between the B3LYP and experiment are slightly larger than for the other two bands. The O₂PPO₂ form of P₂O₄ is 24.5 kcal/mol above the O₂POPO form, but the formation process probably has more to do with the approach geometry of the reactants than with the relative energetics of the two isomers of P₂O₄. This reassignment requires that the 735.1 cm⁻¹ band be due to another species, which grows on annealing in this reactive system. This absorption position and isotopic ratio are characteristic of the PO₃P tribridge (Table 7).

Finally, note the agreement between the B3LYP-calculated frequencies and the five strongest bands assigned to P₄O₁₀ in solid argon¹⁴ (1408, 1026, 767, 577, and 412 cm⁻¹). Again the calculated frequencies (see Table 10) must be scaled upward (in contrast to HF calculations) with scale factors 1.026, 1.050, 1.046, 1.053, and 1.051 for these infrared bands. The size of these scale factors is consistent with those found for O₂PPO₂.

Since bands associated with P₄ are clearly seen in these experiments, we have also considered P₃O and P₄O, which are possible products of the reaction of P₄ with oxygen. The results of these calculations are summarized in Tables 11 and 12. We have considered several structures for each system, but we have

^a The relevant experimental bands from Table 4 are given in parentheses for comparison.

V. Conclusions

The computed frequencies and experiment suggest that the band at 480.3 cm⁻¹ should be reassigned to PO₃⁻. The computed results show that the related band at 1273.3 cm⁻¹ also agrees much better with PO₃⁻ than PO₃. This reassignment is a clear example of the synergistic effect of applying both theory and experiment to the identification of IR bands.

The computed results also suggest that the observed electronic

transition is correctly assigned as the ²E' ← X²A₂' band system of PO₃. The new experimental work does not show any infrared evidence for PO₃, but we are able to identify bands associated with PO₂, PO₂⁻, P₂O, OPOPO, and O₂PPO₂. P₄ is also observed in experiment, but we are unable to observe any evidence for the expected products such as P₄O and P₃O.
