Received: December 6, 1999; In Final Form: March 2, 2000

Heats of formation for  $C_nF_m$ ,  $C_nF_m^+$ ,  $CHF_m$ , and  $CHF_m^+$  compounds are computed at the G3MP2 level. Calibration calculations are presented for  $C_2F_2$ ,  $C_2F$ ,  $CHF$ , and  $CHF_2$ . The results of these calibration calculations, in conjunction with the results of previous high-level calculations, show that the G3MP2 approach is accurate to  $\pm 2$  kcal/mol for these systems. The trends in bond energies are discussed.

## 1. Introduction

Fluorocarbon plasmas, which contain both neutrals and ions, are used in the etching of silicon and silica. In addition to being the etching agent, the fluorocarbons are the feedstock for the formation of the protective polymer overlayer. Thus to fully model the etching requires accurate thermochemical data for both the neutrals and the cations. The data in the commonly used compilations<sup>1,2</sup> are incomplete. While there has been more recent work, as discussed by Ruscic et al.,<sup>3</sup> the newer results do not always lead to an improved, more consistent set of data. While there have been computational studies<sup>4–6</sup> for some of these systems, our goal is to generate a complete set of thermochemical data of equivalent accuracy.

In this manuscript we report the heats of formation of  $CF_n$  and  $CF_n^+$ , for  $n = 1–4$ ,  $CHF_n$  and  $CHF_n^+$ , for  $n = 1–3$ ,  $C_2F_n$  and  $C_2F_n^+$ , for  $n = 1–6$ , and  $C_3F_n$  and  $C_3F_n^+$ , for  $n = 1–8$ . We use the recently developed G3MP2 approach.<sup>7</sup> Highly accurate studies<sup>6</sup> support the use of the G3MP2 approach for these fluorine-containing compounds. Since some of the largest errors in the earlier Gn methods occur for halogen-containing molecules, additional highly accurate calculations are performed to calibrate the G3MP2 approach.

## 2. Methods

The G3MP2 calculations are performed as presented by Pople and co-workers<sup>7</sup> and by using Gaussian 98.<sup>8</sup>

The calibration calculations follow our previous work.<sup>6</sup> Namely, the geometries are determined at the B3LYP/6-31+G-(2df) level<sup>9–11</sup> and the zero-point energies computed using the B3LYP/6-31+G\* approach. The atomization energies are computed using the restricted coupled cluster singles and doubles approach<sup>12,13</sup> including the effect of connected triples determined using perturbation theory,<sup>14,15</sup> RCCSD(T). In the valence RCCSD(T) calculations, the H 1s electron and the C and F 2s and 2p electrons are correlated. In most calculations, the H and C basis sets are the correlation consistent valence polarized (cc-pV) sets developed by Dunning co-workers,<sup>16–19</sup> while the F basis sets are the augmented (aug) cc-pV basis sets.<sup>18,19</sup> In some cases, the aug-cc-pV sets are also used for H and C. The double- $\zeta$  (DZ), triple- $\zeta$  (TZ), quadruple- $\zeta$  (QZ), and quintuple- $\zeta$  (5Z) sets are used. To improve the accuracy of the CCSD(T) results, we extrapolate to the complete basis set (CBS) limit. We use the two-point ( $n^{-4}$ ), three-point ( $n^{-4} + n^{-6}$ ) and variable  $\alpha$  ( $n^{-\alpha}$ ) schemes described by Martin<sup>20</sup> and the two-point  $n^{-3}$  scheme described by Helgaker et al.<sup>21</sup> We denote these schemes as n4, n4n6,  $\alpha$ , and n3, respectively.

The core-valence (CV) effect is computed at the RCCSD(T) level, as the difference between the treatment correlating only the valence electrons and the treatment in which the 1s electrons are also correlated. These calculations are performed using the CV basis set, which is derived from the C and F aug-cc-pV sets. We use the CV(tz), CV(qz), and CV(5z) sets described previously.<sup>22</sup> The aug-cc-pV H sets are used in conjunction with the CV sets.

The atomic spin-orbit effects are computed using the tabulation of Moore.<sup>23</sup> The scalar relativistic effects are computed as the differences between the results obtained using the nonrelativistic and the Douglas Kroll (DK) approaches.<sup>24</sup> More specifically, the systems are studied at the modified coupled pair functional<sup>25</sup> (MCPf) level of theory using the H and C cc-pVTZ and F aug-cc-pVTZ sets. Note that the contraction coefficients used in the molecular DK calculations are taken from DK atomic Hartree-Fock (HF) calculations.

The B3LYP calculations are performed using Gaussian 98,<sup>8</sup> the CCSD(T) calculations are performed using Molpro,<sup>26</sup> and the MCPf calculations are performed using Molecule-Sweden.<sup>27</sup> The DK integrals are computed using a modified version of the program written by Hess.

## 3. Results and Discussion

In Table 1 we compare the core-valence contribution to the atomization energy of CF,  $CF^+$ , CH, and CHF. These species are sufficiently small that it is possible to use the CV(5z) basis set. The agreement among the three basis sets and the agreement with and without including the basis set superposition error (BSSE) is very good. On the basis of these calculations we compute the CV contribution using the CV(tz) set and do not include the BSSE correction. This approximation dramatically reduces the cost of the calculations while introducing only a small error in the core-valence contribution to the atomization energy.

In Tables 2 and 3 we summarize our results for  $C_2F_2$ ,  $C_2F$ , CHF, and  $CHF_2$ . Also given are the previously published<sup>6</sup>  $CF_4$  and  $C_2F_4$  results. We first note that the trends in the atomization energies using the different extrapolation methods are similar for all of the molecules considered. These results show that the 5Z basis set must be used to obtain accurate results, and once the 5Z results are included in the extrapolation, the n4n6-{T,Q,5}Z,  $\alpha$ {T,Q,5}Z, n3{Q,5}Z, and n4{Q,5}Z approaches are in reasonable agreement. Since the n4n6 results give the best agreement with experiment for  $CF_4$ , this approach is used

<sup>a</sup> The CF<sub>4</sub> and C<sub>2</sub>F<sub>4</sub> values are taken from previous work.<sup>6</sup> <sup>b</sup> The ZPE values for CF<sub>4</sub> and C<sub>2</sub>F<sub>4</sub> are taken from previous work,<sup>6</sup> while the ZPE for C<sub>2</sub>F<sub>2</sub> is taken from the B3LYP/6-31+G\* results. <sup>c</sup> The atomization energy is computed as CCSD(T) n4n6{T,Q,5}Z + ΔCV + spin orbit + ZPE + scalar relativistic. <sup>d</sup> The ΔH<sub>298</sub> values are from Table 5 which are given for comparison.

to determine our CCSD(T) CBS values. This is corrected for scalar relativistic, core-valence, and spin-orbit effects, as well as for the zero-point energy (ZPE). The correction from 0 to 298 K is made using the rigid rotor/harmonic oscillator approximation. The same procedure, excluding the scalar relativistic contribution to the atomization energy, was previously<sup>22</sup> used for CF, CF<sub>2</sub>, CF<sup>+</sup>, and CF<sub>2</sub><sup>+</sup>. Therefore, in this work, we compute the scalar relativistic effects and add them to the previous atomization energies; this is summarized in Table 4.

In Tables 2–4, the accurate atomization energies are converted to heats of formation using the well-known heats of formation<sup>2</sup> for H, C, and F. The G3MP2 values are also given in Tables 2–4, and the G3MP2 values agree with the high-level calculations to better than 2 kcal/mol. The G3MP2 atomization energies are slightly larger than those found in the higher level calculations. We should note that Ruscic et al.<sup>3</sup> found that the G3 heats of formation for some carbon-halogen systems were about 1 kcal/mol more negative than experiment. Thus both the G3 and G3MP2 approaches appear to yield an atomization energy that is slightly too large.

<sup>a</sup> The previous values<sup>22</sup> corrected for scalar relativistic effects.

The calibration calculations support the use of the G3MP2 approach for these systems. The G3MP2 atomization energies at 0 K and heats of formation, at both 0 and 298 K, are given in Table 5. Also included in Table 5 are the results of Gurvich et al.<sup>1</sup> In general, we report the G3MP2 results only for the most stable isomer; for a few systems we also report the results for more than one state or isomer in Table 5. For C<sub>2</sub>, there are two low-lying states, and the G3MP2 approach correctly predicts a <sup>1</sup>Σ<sub>g</sub><sup>+</sup> ground state. The <sup>3</sup>Π<sub>u</sub> state is computed to be 4.38 kcal/mol higher in energy, which is to be compared with the experimental value<sup>28</sup> of 1.74 kcal/mol. For C<sub>2</sub>F<sub>2</sub> and C<sub>2</sub>F<sub>4</sub>, we also report results for the CCF<sub>2</sub> and FCCF<sub>3</sub> isomers (which are higher in energy than FCCF and F<sub>2</sub>CCF<sub>2</sub>, respectively), since these can be produced by the fragmentation of C<sub>3</sub>F<sub>n</sub> species. For C<sub>3</sub>F<sub>2</sub> and C<sub>3</sub>F<sub>2</sub><sup>+</sup>, we consider the two possible structures, FCCCF and CCCF<sub>2</sub>. For FCCCF, we also consider both the singlet and triplet states. The most stable form is the singlet state of CCCF<sub>2</sub>. It is interesting to note, however, that FCCCF<sup>+</sup> is more stable than CCCF<sub>2</sub><sup>+</sup>. Starting from C<sub>3</sub>F<sub>8</sub>, two isomers of C<sub>3</sub>F<sub>7</sub> can be formed by removing a F atom attached to the terminal or the central C. We consider both forms of C<sub>3</sub>F<sub>7</sub>, and for the neutral, we find that it is favorable to remove the F on

C <sub>3</sub> F <sub>8</sub> <sup>+</sup> (F <sub>3</sub> C(CF <sub>2</sub> )CF <sub>3</sub> )	1043.93	-126.56	-126.89	

the central carbon, while for the cation it is more favorable to remove the F on the terminal carbon atom.

The heats of formation of CF<sub>4</sub>, CF<sub>3</sub>, CF<sub>3</sub><sup>+</sup>, C<sub>2</sub>F<sub>4</sub>, and FCCF<sub>3</sub> in Table 5 agree well with the high-level calculations of Dixon et al.<sup>4</sup> The largest difference is 2.5 kcal/mol for CF<sub>3</sub><sup>+</sup> and the second largest difference is 1.1 kcal/mol for C<sub>2</sub>F<sub>4</sub>. This is not surprising since their high-level computational approach is very similar to our high-level calibration calculations. Our results agree to within 2 kcal/mol with the results of Zachariah et al.<sup>5</sup> for CF, CF<sub>2</sub>, CF<sub>3</sub>, CF<sub>4</sub>, CHF<sub>2</sub>, CHF<sub>3</sub>, C<sub>2</sub>F, C<sub>2</sub>F<sub>3</sub>, C<sub>2</sub>F<sub>5</sub>, and C<sub>2</sub>F<sub>6</sub>. For CHF, C<sub>2</sub>F<sub>2</sub>, and C<sub>2</sub>F<sub>4</sub>, we differ by 3.0, 7.6, and 5.5 kcal/mol, respectively. For these three systems they assign error bars

of ±3.9, ±6.5 and ±4.0 kcal/mol. Since the G3MP2 has an error bar of ±2 kcal/mol, even for these systems, the two methods agree to within their mutual uncertainties. Our high-level calibration calculations support our values over those of Zachariah et al.

The agreement between theory and the work of Gurvich et al.<sup>1</sup> is somewhat mixed. For the species with one carbon atom, theory and experiment are in good agreement for all systems except CF<sub>2</sub> (N.B. that the Gurvich et al. value for CHF is only an estimate). The high-level treatment for CF<sub>2</sub> (-45.6 kcal/mol) is at the lower limit of the experimental value (-43.0 ± 2.4 kcal/mol), suggesting that the G3MP2 value is about 2 kcal/mol too negative. That is, the true result probably lies between experiment and the G3MP2 value. The high-level calculations for CHF yield a slightly larger value than the G3MP2 approach (35.8 vs 34.5 kcal/mol). Thus we conclude that the estimate is even less accurate than the large error bar would imply.

For the systems with two carbon atoms, the agreement between theory and experiment is not as good as found for the single carbon systems. For C<sub>2</sub> the G3MP2 and Gurvich values differ by 6 kcal/mol. Using a more recent<sup>29</sup> experimental atomization energy yields a C<sub>2</sub> heat of formation at 298 K of 196.3 kcal/mol, which shows that the Gurvich value is a bit too large but that the G3MP2 value is too small by 3.5 kcal/mol. While the error at the G3MP2 level is larger than the desired 2 kcal/mol accuracy, C<sub>2</sub> is known to be a very difficult problem. We note however, that high-level calculations<sup>30</sup> yield an atomization energy of 144.6 kcal/mol, which is in good agreement with the experimental<sup>29</sup> atomization energy of 145.2 ± 0.5 kcal/mol. Lowering the Gurvich C<sub>2</sub><sup>+</sup> result by 2 kcal/mol to account for the newer C<sub>2</sub> atomization energy still leaves the G3MP2 value about 6 kcal/mol too small.

The agreement between theory and experiment is good for C<sub>2</sub>F<sub>3</sub>, C<sub>2</sub>F<sub>5</sub>, and C<sub>2</sub>F<sub>6</sub>. The agreement for C<sub>2</sub>F<sub>4</sub> is reasonable, but previous work,<sup>6</sup> which is summarized in Table 2, strongly suggests that the G3MP2 value is closer to the true value than is experiment, despite the small error bars on the experimental result. The experimental value for C<sub>2</sub>F is poorly known and the G3MP2 value is 16 kcal/mol larger than experiment. The calibration value is slightly larger than the G3MP2 value. The experimental C<sub>2</sub>F<sub>2</sub> value is 35 kcal/mol more negative than the G3MP2 value. The calibration calculations show that the experimental value must be wrong for C<sub>2</sub>F and C<sub>2</sub>F<sub>2</sub>.

Ruscic and co-workers have determined the heats of formation at 298 K for CF<sub>3</sub> (-111.3 ± 0.5<sup>3</sup> and -111.4 ± 0.9<sup>31</sup>), CHF<sub>3</sub> (-165.6 ± 0.5 kcal/mol<sup>3</sup>), and C<sub>2</sub>F<sub>6</sub> (-321.3 ± 0.8 kcal/mol<sup>3</sup>). These values differ slightly from those by Gurvich and hence are consistent with our G3MP2 values. We should note that these authors believe that the experimental value of C<sub>2</sub>F<sub>4</sub> is in error by up to 2.5 kcal/mol, which is consistent with our results.

The experimental data for C<sub>3</sub>F<sub>n</sub> is very limited. Lias et al.<sup>32</sup> give -426 ± 2 kcal/mol for C<sub>3</sub>F<sub>8</sub>, which is in good agreement with the G3MP2 value of -422.0 kcal/mol. Theory and experiment differ by 8 kcal/mol for C<sub>3</sub>. On the basis of C<sub>2</sub>, we would not be surprised to find that the error in the G3MP2 result for C<sub>3</sub> exceeds the desired value of ±2 kcal/mol.

The ionization potentials (IPs) of some of the systems studied have been measured very accurately. In Table 6 we compare our computed G3MP2 IPs with those for systems where experiment is believed to be accurate. Excluding CHF<sub>3</sub> and C<sub>3</sub>F<sub>8</sub>, the computed values are 0.1–0.15 eV larger than experiment.<sup>31,32</sup> An error of this magnitude is consistent with an uncertainty of about 2 kcal/mol in the G3MP2 energies, but suggests that the errors in the neutrals and ions go in opposite

directions or that the experimental error bars are somewhat optimistic. The computed values for CHF<sub>3</sub> and C<sub>3</sub>F<sub>8</sub> are smaller than experiment. We suspect this is due to experiment not obtaining the adiabatic IP. For the saturated systems such as CF<sub>4</sub>, CHF<sub>3</sub>, and C<sub>3</sub>F<sub>8</sub>, the cations are weakly bound charge-induced dipole complexes; thus, CF<sub>4</sub><sup>+</sup> is CF<sub>3</sub><sup>+</sup>...F, CHF<sub>3</sub><sup>+</sup> is CHF<sub>2</sub><sup>+</sup>...F, and C<sub>3</sub>F<sub>8</sub><sup>+</sup> is C<sub>3</sub>F<sub>5</sub><sup>+</sup>...CF<sub>3</sub>. For this type of complex, it would be difficult to obtain the adiabatic IP because of a very small Franck–Condon factor, and therefore, we believe that the best estimate for the adiabatic IP of these systems is 0.1 eV smaller than our computed value. Finally we should note that C<sub>2</sub>F<sub>6</sub><sup>+</sup> is a CF<sub>3</sub><sup>+</sup>...CF<sub>3</sub> complex, but it is somewhat more bound than the other saturated systems, because of resonance charge exchange, i.e., CF<sub>3</sub><sup>+</sup>...CF<sub>3</sub> ↔ CF<sub>3</sub>...CF<sub>3</sub><sup>+</sup>.

In conclusion, the calibration calculations support the view that on average the G3MP2 approach is accurate to ±2 kcal/mol. The accurate experimental results, excluding C<sub>2</sub> and C<sub>2</sub>F<sub>4</sub>, also support this view. Highly accurate calculations<sup>6</sup> for C<sub>2</sub>F<sub>4</sub> support the accuracy of the G3MP2 approach. Experiment suggests that the errors in the G3MP2 treatment of C<sub>2</sub> are larger than 2 kcal/mol. It is possible that the error in the G3MP2 treatment of C<sub>3</sub> also exceeds 2 kcal/mol. Thus, excluding C<sub>2</sub> and C<sub>3</sub>, the G3MP2 approach should yield the most complete and accurate set of data for the C<sub>n</sub>F<sub>m</sub>, C<sub>n</sub>F<sub>m</sub><sup>+</sup>, CHF<sub>m</sub>, and CHF<sub>m</sub><sup>+</sup> systems.

Selected bond energies for CF<sub>n</sub>, CF<sub>n</sub><sup>+</sup>, CHF<sub>n</sub>, and CHF<sub>n</sub><sup>+</sup> are reported in Table 7. While the first, second, and fourth C–F bonds in CF<sub>n</sub> are similar, the third bond is weaker, because carbon must change hybridization to form three bonds. The trends for CF<sub>n</sub><sup>+</sup> are very different. CF<sup>+</sup> is much more strongly bound than CF, presumably due to F donation into empty C π orbitals. The second bond is much weaker since the C<sup>+</sup> has to hybridize to form a second bond. The third bond is strong, but not as strong as the first, probably because the electrostatic interaction for each bond is weaker since it is spread over three bonds. The fourth bond is weak, as C<sup>+</sup> only has three valence electrons. The results for CHF<sub>n</sub> and CHF<sub>n</sub><sup>+</sup> are similar to those found for CF<sub>n</sub> and CF<sub>n</sub><sup>+</sup>. The only exception is for CH and CH<sup>+</sup>, which have similar bond energies since hydrogen has no π lone pairs to donate to the carbon.

Selected bond energies for C<sub>2</sub>F<sub>n</sub> and C<sub>2</sub>F<sub>n</sub><sup>+</sup> are reported in Table 8. One observation is that for C<sub>2</sub>F<sub>n</sub><sup>+</sup> it is easier to break

<sup>a</sup> The neutral form is CCCF<sub>2</sub>.

the C–C bond than a C–F bond. This is consistent with the appearance potentials<sup>33</sup> for C<sub>2</sub>F<sub>6</sub>, C<sub>3</sub>F<sub>6</sub>, and C<sub>3</sub>F<sub>8</sub>, which show a breaking of the C–C bonds before breaking of the C–F bonds. The breaking of the C–C bonds before the C–F bonds is even true for C<sub>2</sub>F<sub>2</sub><sup>+</sup> and C<sub>2</sub>F<sub>4</sub><sup>+</sup>, which have C–C multiple bonding. For the neutrals, the C–C bonds are weaker than the C–F bonds, except for C<sub>2</sub>F. To form multiple C–C bonds, CF<sub>2</sub> and CF must promote to the triplet and quartet states, respectively. This promotion energy is much larger for CF<sub>2</sub> and CF than the analogous promotion energies for CH<sub>2</sub> and CH, and therefore, the C–F bonds weaken the C–C π bonds. Thus it is far more favorable to break C–C multiple bonds in the C<sub>x</sub>F<sub>y</sub> systems than in the analogous C<sub>x</sub>H<sub>y</sub> systems.

Selected bond energies for C<sub>3</sub>F<sub>n</sub> and C<sub>3</sub>F<sub>n</sub><sup>+</sup> are given in Table

9. For  $C_3F_8^+$  and  $C_3F_7^+$ , breaking a C–C bond is easier than breaking a C–F bond. For the species with fewer F atoms, it tends to be easier to remove a F atom than to break a C–C bond; this is different from  $C_2F_n^+$ . For the neutrals, the species with an even number of F atoms tend to have stronger C–F bonds than C–C bonds, while those with an odd number of F atoms are open-shell systems, which would rather lose a F atom to become closed-shell than break a C–C bond.

The heat capacity, entropy, and temperature dependence of the heat of formation are computed for 300–4000 K using a rigid rotor/harmonic oscillator approximation. The scaled HF frequencies are used in these calculations. These results are fit in two temperature ranges, 300–1000 and 1000–4000 K using the Chemkin<sup>34</sup> fitting program and following their constrained three-step procedure. The parameters obtained from the resulting fits can be found on the Web.<sup>35</sup>

#### 4. Conclusions

We have performed highly accurate calibration calculations for several species, which support the use of the G3MP2 approach. There is reasonable agreement between theory and experiment for most systems. The only obvious problems with the G3MP2 approach arise for  $C_2$  and  $C_3$ , where the errors are about 4 and 6 kcal/mol, whereas the rest of the systems appear to be accurate to about  $\pm 2$  kcal/mol. The heat capacity, entropy, and temperature dependence of the heat of formation are fit to 14 parameters that can be found on the Web.<sup>35</sup>
