#### Abstract

$\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}$ and $\mathrm{H}_{3} \mathrm{BXH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As$)$ have been studied as donor-acceptor complex type at the G2(MP2) level of theory. Both single- and double-bridged structures of $\mathrm{B}_{3} \mathrm{H}_{7}$ Lewis acid are taken into account. Although the double-bridged structure is energetically favored in the isolated state, the coordination prefers the single-bridged one. The monoborane adducts adopt the staggered arrangement with $C_{3 v}$ symmetry. The energetic analysis by natural bond orbital theory shows that the decrease of hyperconjugative contribution upon complexation in the $\mathrm{B}_{3} \mathrm{H}_{7}$ moiety has, as consequence, a loss of symmetry for $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{P}$ and As) complexes. In the two series, the coordination is the result of two opposing interactions. The first one is stabilizing, developed between $a^{\prime}$ symmetry fragment molecular orbitals, and is mainly of 3MO-4e nature. The second one is destabilizing and developed between occupied molecular orbitals ( $2 \mathrm{MO}-4 \mathrm{e}$ ) of donor and acceptor fragments having $a^{\prime \prime}$ symmetry. Furthermore, in the case of $\mathrm{BH}_{3}$ complexes, the complexation is made along the $C_{3}$ axis that joined the two fragments, whereas for $\mathrm{B}_{3} \mathrm{H}_{7}$, it is mainly centered on the nonequivalent boron atom, but the two other ones are also weakly involved in the coordination through a suitable p orbital even if the donor fragment is not on the three boron triangle center.

## 1. Introduction

A typical property of electron-deficient boranes is their Lewis acidity, which reflects the fact that boron possesses fewer valence electrons than valence orbitals; ${ }^{1}$ they react readily with a range of Lewis bases in both solution and gas phase. However, this property differs from small boranes to higher borane clusters because the boron connectivity increases when the number of borons in the clusters increases. Indeed, the structural chemistry of higher boranes is dominated by deltrahedra, cluster shapes composed of numerous triangles formed with three boron atoms. Thus, it's more interesting to compare the complex stability formed by reaction of monoborane $\left(\mathrm{BH}_{3}\right)$ and triborane $\left(\mathrm{B}_{3} \mathrm{H}_{7}\right)$ with Lewis bases such as $\mathrm{NH}_{3}, \mathrm{PH}_{3}$, and $\mathrm{AsH}_{3}$.

The stability and properties of $\mathrm{BH}_{3} \mathrm{~L}$ complexes ( $\mathrm{L}=$ Lewis base) are sufficiently studied ${ }^{2-18}$ and carried out. In the case of those Lewis acid-base complexes, it was shown that the stability of the formed donor-acceptor adducts depends on the nature of the ligand and $\mathrm{BH}_{3}$ acid substituent. Therefore, Anane et al. ${ }^{17,18}$ have shown that the complexes formed with $\mathrm{BH}_{3}$ and $\mathrm{XH}_{3}(\mathrm{X}=\mathrm{P}$ and N$)$ are found to be more stable than those obtained with $\mathrm{XH}_{2}(\mathrm{X}=\mathrm{O}$ and S$)$ than with $\mathrm{XH}(\mathrm{X}=\mathrm{F}$ and $\mathrm{Cl})$ at the G 2 level of theory. They have also shown that $\mathrm{H}_{3}-$ $\mathrm{BNH}_{3}$ is more stable than $\mathrm{H}_{3} \mathrm{BPH}_{3}$ and that the s character of the $\mathrm{B}-\mathrm{X}$ bond decreases and p character increases as the electronegativity of X increases. They have concluded that the $\mathrm{B}-\mathrm{X}$ bond cannot be treated only in terms of a simplest HOMO-LUMO interaction model (two level and two electron model system: 2MO-2e), but the interaction occurs between two molecular orbitals of the acceptor (LUMO and a deeper

[^0]orbital) and the highest occupied molecular orbital (HOMO) of the donor (a three level and four electron model system: $3 \mathrm{MO}-4 \mathrm{e}$ )

They have also illustrated that the complexation energies depend on the degree of substitution on the acceptor and donor fragments. In recent studies, our group ${ }^{19,20}$ has investigated $\mathrm{H}_{3}$ $\mathrm{AlXR}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and $\mathrm{As}, \mathrm{R}=\mathrm{H}$ and Me$)$ as donor-acceptor complex types at the G2(MP2) level of theory. The stability of these complexes decreases when going from nitrogen to arsenic, and the evolution of the complexation energy of $\mathrm{H}_{3} \mathrm{AlXR}_{3}$ adducts depends on the coordination mode; this is a result of two interaction types: a stabilizing interaction between $a_{1}$ symmetry fragment molecular orbitals and a destabilizing interaction between $e$ ones. The stability of donor-acceptor complexes formed by $\mathrm{B}_{3} \mathrm{H}_{7}$ borane as Lewis acid and different Lewis bases is not sufficiently studied. However, the stability of isolated $\mathrm{B}_{3} \mathrm{H}_{7}$ conformations was largely carried out. In fact, Lipscomb et al. ${ }^{21}$ have shown that the favored structure is that having two bridged hydrogen atoms (double-bridged: 2102 structure in styx notation ${ }^{22}$ ) compared to the structure with one bridged hydrogen atom (single-bridged: 1103 structure in styx notation) by above $4.4 \mathrm{kcal} / \mathrm{mol}$. Experimentally, it was shown that the $\mathrm{B}_{3} \mathrm{H}_{7}$ moiety has only one bridged hydrogen in $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{~L}$ ( $\mathrm{L}=\mathrm{NH}_{3}$ and CO ) compounds. ${ }^{23-25}$ Thus, when the ligand is removed, the $\mathrm{B}_{3} \mathrm{H}_{7}$ unit has a vacant orbital, which can be filled with some strain by conversion of a terminal hydrogen of the single-bridged structure to the double-bridged one. Morokuma et al. ${ }^{26}$ have investigated the stability and the structure of both $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{CO}$ at the MP2/6-31G level of theory. They have shown that the $\mathrm{B}_{3} \mathrm{H}_{7}$ species in these complexes prefers the single-bridged arrangement.

In continuation of our work, we now report our investigation of the $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) donor-acceptor complexes

Figure 1. Optimized single- and double-bridged structures of isolated $\mathrm{B}_{3} \mathrm{H}_{7}$ borane.
compared to the $\mathrm{H}_{3} \mathrm{BXH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) ones. The relative stability of these complexes is examined with respect to the qualitative molecular orbital analysis (QMOA)..$^{27,28}$ To the best of our knowledge, no comparative study of these complexes has been carried out.

## 2. Computational Details

Ab initio calculations were performed using the Gaussian 98 series of computer programs ${ }^{29}$ on the IBM RS/ 6000 workstations at the University of València. Geometry optimizations were performed at the MP2(full)/6-31G(d) level; the zero-point vibrational energies (ZPE) are obtained from scaled HF/6-31G(d) frequencies (scaled by the factor 0.893). ${ }^{30}$ For improved energy, the G2(MP2) energies ${ }^{31}$ were computed. The electronic structures have been done using the natural bond orbital (NBO) ${ }^{32}$ partitioning scheme at the MP2(full)/6-31G(d) level. NBOs are the localized set of easily recognizable Lewis-like ( $\sigma$ and $\pi$ bond, lone pair, and core) and non-Lewis ( $\sigma^{*}$ and $\pi^{*}$ antibond and Rydberg) orbitals, which are optimal in the sense of orthonormality and maximum occupancy of the Lewis set. An important feature of the NBO method is that unlike other charge partitioning schemes, the presence of diffuse functions in the basis sets does not significantly affect the result. ${ }^{32}$ On another hand, we did not correct for the basis set superposition errors (BSSE), which should be relatively small with a large basis set such as $6-311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p})$. Moreover, a study by Mikhali et al., ${ }^{33}$ using the G2 $(+)$ method, and more recently a study by Mo and $\mathrm{Gao}^{34}$ show that the BSSE has little effect on the calculated complexation energies.

## 3. Results and Discussion

3.1. Geometries. First, we proceeded to the structural study of the series of $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}, \mathrm{~B}_{3} \mathrm{H}_{7} \mathrm{PH}_{3}$, and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{AsH}_{3}$ compounds. Taking into account both $C_{2 v}$ and $C_{s}$ structural conformations of the $\mathrm{B}_{3} \mathrm{H}_{7}$ fragment (Figure 1), we made two corresponding approaches by imposing the $C_{s}$ symmetry. Let us remember that

TABLE 1: G2(MP2) Total Energies (in au) of $\mathbf{B}_{3} \mathbf{H}_{7} \mathbf{X H}_{3}$ Complexes

${ }^{a} \Delta E(\mathrm{kcal} / \mathrm{mol})$ is the difference in energy above the minimum energy conformation.
the double-bridged structure of isolated $\mathrm{B}_{3} \mathrm{H}_{7}$ is more stable than the single-bridged one. ${ }^{35,36}$ In this work, we have reexamined this stabilization; it is about $3.7 \mathrm{kcal} / \mathrm{mol}$ at the G2(MP2) level of theory.

As we will show below, the LUMO that confers the Lewis acid property to $\mathrm{B}_{3} \mathrm{H}_{7}$ is localized on the $\mathrm{B}_{1}$ boron atom in both single- and double-bridged conformations. Nevertheless, this latter structure would be a bad acceptor via the $B_{1}$ atom. In fact, if we compare these two structures, we note that $B_{1}$ is not as accessible in the $C_{s}$ double-bridged triborane as in the $C_{2 v}$ single-bridged one. In the $C_{2 v}$ conformation, the $\mathrm{B}_{1}$ atom is practically in a similar neighborhood to the $\mathrm{BH}_{3}$ simple system. Thus, we should expect a less-stable complexation when $\mathrm{B}_{3} \mathrm{H}_{7}$ adopts the double-bridged form than when it is in the singlebridged one. Effectively, the collected energetic data (Table 1) confirm it. We notice that for the three complexes, the singlebridged structure is more stable than the double-bridged one. Therefore, the energetic deviations are 8.33, 12.48, and 14.29 $\mathrm{kcal} / \mathrm{mol}$ for $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As, respectively) at the G2(MP2) level of theory. In previous works, only the singlebridged structure has been taken into account; the doublebridged one has been omitted for spectral ${ }^{24,25}$ and energetical ${ }^{26,37}$ considerations. In this work we also considered only the singlebridged structure.

We then reoptimized the three single-bridged complexes $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) without symmetry constraints. In Figure 2, we have reported the favored conformations, which are all minima. In Table 2, we present selected bond lengths in isolated and complexed $\mathrm{B}_{3} \mathrm{H}_{7}$ borane. We remark that there are no important effects of the ligand coordination on the geometry of $\mathrm{B}_{3} \mathrm{H}_{7}$ Lewis acid. We notice that only the $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$ compound keeps $C_{s}$ symmetry, whereas for the two other ones, the $\mathrm{XH}_{3}(\mathrm{X}=\mathrm{P}$ and As) ligand is out of the symmetry plane.

What are the factors behind these structural preferences? To answer this question, we have undertaken a NBO energetic analysis by carrying out interfragments zeroing interactions and Fock matrix elements deletions on $\mathrm{B}_{3} \mathrm{H}_{7}$ free and coordinated fragment. On another hand, the thorough examination of fragments' donor and acceptor structural, and orbital interactions and coordination energy evolution within this series will permit, as we will see hereafter, us to confirm factors behind the choice of such geometrical preferences.
3.2. NBO Energetic Analysis. We considered free $\mathrm{B}_{3} \mathrm{H}_{7}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) compounds taken in their symmetries ( $C_{2 v}$ for free $\mathrm{B}_{3} \mathrm{H}_{7}$ and $C_{s}$ for the others). We took only the symmetrical structures with the aim to know factors responsible for the fragment symmetry maintenance of the $\mathrm{B}_{3} \mathrm{H}_{7}$ fragment. This last could be regarded as being formed by a $\mathrm{BH}_{2}$ (Frag1) fragment and a $\mathrm{H}_{2} \mathrm{~B}(\mathrm{H}) \mathrm{BH}_{2}$ (Frag2) one (Scheme 1).

However, slight rotations of the Frag1 unit around the $\mathrm{B}_{1}-$ $\mathrm{H}_{\mathrm{b}} C_{2}$ axis (bisector axis of $\mathrm{HB}_{1} \mathrm{H}$ angle) cause a symmetry loss. This symmetrical breaking is avoided thanks to, among other things, an electronic delocalization between $\mathrm{B}-\mathrm{H}$ bonds $(\sigma)$ of Frag1 unit and antibond lone pairs (LP*) of $\mathrm{B}_{1}$ and $\mathrm{B}_{2}$

Figure 2. Optimized structures of $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) complexes.

atoms or between $\sigma\left(\mathrm{B}_{1,2}-\mathrm{H}\right) \mathrm{NBOs}$ and LP (or LP*) ones of $\mathrm{B}_{1}$ atom. Those delocalizations are as much best as Frag1 B-H bonds are in the three-boron atoms plane. Two qualitative deletions have been considered. The first one is the Frag1 and Frag2 zeroing interaction. The corresponding energies could be considered close at this level of theory (Table 1). This interaction is a result of Lewis-Lewis and Lewis-non-Lewis Frag1 and Frag2 NBOs mixtures. The second deletion is the elimination of two Fock-matrix element sets that have a significant role in the Frag1-Frag2 interaction. However, the elimination of

## SCHEME 1

elements corresponding to $\operatorname{LP}\left(\mathrm{B}_{1}\right)-\mathrm{LP} *\left(\mathrm{~B}_{1,2}\right)$ shows that the corresponding interaction does not control the symmetry maintenance of the $\mathrm{B}_{3} \mathrm{H}_{7}$ moiety although its energy represents about $80 \%, 70 \%$, and $50 \%$ of the total energy of the Frag1Frag2 interaction for $\mathrm{B}_{3} \mathrm{H}_{7}, \mathrm{~B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$, and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{P}$ and As), respectively (Table 3). In fact, it is not too sensitive to the symmetry breaking by turning the Frag1 unit around the $C_{2}$ axis. This interaction contributes to the three-centers twoelectron (3c-2e) bonding. ${ }^{1}$ The second deletion corresponds to sets of elements that ensure the $\sigma(\mathrm{B}-\mathrm{H})$ of one fragment and LP (or LP*) NBOs of boron atom of the other one. However, because this interaction implies out of three boron's ring B-H bonds, its relative energy values give an idea of its capability to control the symmetry loss. The corresponding energy is about 54,41 , and $9 \mathrm{kcal} / \mathrm{mol}$ for free $\mathrm{B}_{3} \mathrm{H}_{7}, \mathrm{~B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$, and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}$ ( $\mathrm{X}=\mathrm{P}$ and As ), respectively and represents $11 \%, 9 \%$, and $2 \%$ of the total Frag1-Frag2 interaction (Table 3). Starting from these values, we can already conclude that $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{PH}_{3}$ and $\mathrm{B}_{3} \mathrm{H}_{7}-$ $\mathrm{AsH}_{3}$ compounds are more likely to lose their symmetry than free $\mathrm{B}_{3} \mathrm{H}_{7}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$ ones. On the other hand, because the interacting NBOs are vicinal, we can also conclude that the symmetry breaking can be related, among other things, to the decrease of the hyperconjugative energetic contribution of Frag1-Frag2 interaction. A weak electrostatic or steric perturbation caused by the ligand could be sufficient to cause a symmetry breaking.
3.3. Structural Analysis. As we will show below, the complexation becomes weaker on going from $\mathrm{NH}_{3}$ to $\mathrm{AsH}_{3}$ fragments. However, the central atom of the donor fragment becomes increasingly bulky. This has the consequence of an increasing long distance $\mathrm{B}-\mathrm{X}$, so the donor fragment becomes increasingly mobile. Thus, small electrostatic or steric interactions could move it to one or the other side of its medium position. In Table 4, we have reported the net charges of the hydrogen atoms that are likely to interact with each other and distances that separate them. However, we note that, from the geometrical point of view, the distance $d_{\mathrm{B} 1-\mathrm{X}}$ increases on going from N to As ( $1.63,1.93$, and $2.00 \AA$, respectively). This is normal because the atomic radius of the donor central atom increases in the even feel $(0.74,1.1$, and $1.21 \AA$ for $\mathrm{N}, \mathrm{P}$, and As, respectively). ${ }^{38}$
This has an effect on the distances between $\mathrm{H}\left(\mathrm{XH}_{3}\right)$ and $\mathrm{H}\left(\mathrm{B}_{3} \mathrm{H}_{7}\right)$ atoms, which increase, and thereafter, their interactions decrease. To illustrate this, we take $d_{\mathrm{H} 1-\mathrm{H} 3}$ distance as an

| $\mathrm{BH}_{3} \mathrm{AsH}_{3}$ | -2262.623433 | -14.67 | 2.05 | 0.598 |

example (Table 4); we note that it increases from $\mathrm{NH}_{3}$ to $\mathrm{AsH}_{3}$ (2.21, 2.66, and $2.70 \AA$, respectively, in $C_{s}$ symmetry and 2.21 , 2.76, and $2.97 \AA$ in $C_{1}$ symmetry, respectively). In $C_{s}$ symmetry, the $\mathrm{H}_{1}$ and $\mathrm{H}_{1^{\prime}}$ atoms, on one hand, and $\mathrm{H}_{3}$ and $\mathrm{H}_{3^{\prime}}$ atoms, on the other hand, are of like charge sign in the $\mathrm{PH}_{3}$ and $\mathrm{AsH}_{3}$ cases and oppositely charged in the $\mathrm{NH}_{3}$ one. Indeed, this symmetry imposes to $\mathrm{H}_{1}-\mathrm{H}_{3}$ and $\mathrm{H}_{1^{\prime}}-\mathrm{H}_{3^{\prime}}$ interactions the same intensities and same natures (repulsive or attractive). The $\mathrm{B}_{3} \mathrm{H}_{7}{ }^{-}$ $\mathrm{PH}_{3}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{AsH}_{3}$ complexes are transition states and the $\mathrm{B}_{3} \mathrm{H}_{7}-$ $\mathrm{NH}_{3}$ complex is a minimum on the $C_{s}$ symmetry potential surface. For the $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{PH}_{3}$ compound, in $C_{1}$ symmetry, the rotation of the $\mathrm{PH}_{3}$ axis group around $\mathrm{P}-\mathrm{B}_{1}$ and the P atom output from the median plane lead to a new geometrical repositioning of the $\mathrm{H}_{1}$ and $\mathrm{H}_{1^{\prime}}$ atoms with respect to the $\mathrm{H}_{3}$ and $\mathrm{H}_{3^{\prime}}$ ones (Figure 2). In fact, $\mathrm{H}_{3^{\prime}}$ (negatively charged) moves to 2.88 and $2.73 \AA$ from $\mathrm{H}_{1}$ and $\mathrm{H}_{1^{\prime}}$, respectively, which are both positively charged, whereas $\mathrm{H}_{3}$ (positively charged) is at $2.76 \AA$ from $\mathrm{H}_{1}$. Thus lateral double-attraction $\left(\mathrm{H}_{1}-\mathrm{H}_{3^{\prime}}\right.$ and $\mathrm{H}_{1^{\prime}}-\mathrm{H}_{3^{\prime}}$ ) and repulsion $\left(\mathrm{H}_{1}-\mathrm{H}_{3}\right)$ take place and favor the $C_{1}$ structure. We notice that this latter corresponds to a minimum in the total potential energy surface. The same remark can be made concerning the $\mathrm{AsH}_{3}$ complex (Figure 2 and Table 4). One can thus conclude that the interactions between these hydrogen atoms favor $C_{1}$ symmetry for $\mathrm{PH}_{3}$ and $\mathrm{AsH}_{3}$ adducts and do not for the $\mathrm{NH}_{3}$ complex. Being given that, the attractive and repulsive interactions between hydrogen atoms in both cases have a decisive role in the structure choice. Let us note that although these interactions are weak, they affect the structural form solely if the coordination is also weak, that is, when the ligand is not strongly bound to the acceptor and could be easily moved out of its symmetrical position. This is confirmed by the low energy difference between the $C_{s}$ structure and $C_{1}$ one ( 0.30 and $1.33 \mathrm{kcal} / \mathrm{mol}$ at G2(MP2) level of theory for $\mathrm{B}_{3} \mathrm{H}_{7}-$ $\mathrm{PH}_{3}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{AsH}_{3}$, respectively (Table 1)) or by the complexation energy, which decreases from the corresponding $\mathrm{NH}_{3}$ compound to the $\mathrm{AsH}_{3}$ one (Table 5).

Concerning the analogous compounds having $\mathrm{BH}_{3}$ as the acceptor, the staggered conformation is energetically favored with a perfect $C_{3 v}$ symmetry. According to our reasoning and compared to $\mathrm{B}_{3} \mathrm{H}_{7}$ compounds, we would expect that there

$$
\mathrm{B}_{3} \mathrm{H}_{7} \quad \mathrm{~B}_{3} \mathrm{H}_{7}-\mathrm{NH}_{3} \quad \mathrm{NH}_{3}

Figure 3. Fragmental analysis of the " $a$ "" symmetry molecular orbitals of (a) $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$, (b) $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{PH}_{3}$, and (c) $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{AsH}_{3}$.
would be no change concerning the symmetrical properties. This is especially controlled by atomic interactions between hydrogens. Indeed, each hydrogen atom of one fragment is exactly in the same geometrical environment as the two others, consequently the H (acceptor) -H (donor) interactions have the same intensity and the same nature. Contrary to $\mathrm{B}_{3} \mathrm{H}_{7}$ cases, this does not favor the symmetry reduction; thus all corresponding complexes kept the staggered $C_{3 v}$ symmetry.

3.4. Qualitative Molecular Orbitals Analysis. As we have mentioned in the Introduction, we showed that there are two interaction types that manage the $\mathrm{AlH}_{3}$ complexation with $\mathrm{NH}_{3}$, $\mathrm{PH}_{3}$, and $\mathrm{AsH}_{3}{ }^{19}$ In the present work, the same remarks have been noted for the $\mathrm{BH}_{3} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) complexation. The first one is stabilizing and occurs between the higher $a^{\prime}$ molecular orbitals of both donor and acceptor fragments, whereas the second one occurs between $a^{\prime \prime}$ ones. This latter has a destabilizing character because its interacting orbitals are occupied. The coordination is a mixture of these two interactions but is globally stabilizing, and the evolution of the complexation energy is decreasing along the donor central atom column of the periodic table from N to As.

Similarly to the $\mathrm{BH}_{3}$ adducts case, the $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) coordination is governed by stabilizing and destabilizing interactions. The first one is the seat of a mixture between $a^{\prime}$ molecular orbitals of both acceptor and donor fragments. In this interaction, the acceptor fragment principally participates in the LUMO. Another orbital is also concerned by this interaction; it is that developed on both $p$ atomic orbitals implying in the four $\mathrm{B}-\mathrm{H}$ bonds of $\mathrm{BH}_{2}$ bridged fragments (Figure 3). However, although the coordination of the two Lewis acids $\left(\mathrm{BH}_{3}\right.$ and $\mathrm{B}_{3} \mathrm{H}_{7}$ ) is almost the same from the energetic point of view, their coordination mode is different because $\mathrm{B}_{3} \mathrm{H}_{7}$ involves the three boron atoms. In fact, for the $\mathrm{BH}_{3}$ Lewis acid, the complexation is made perfectly along the $C_{3}$ axis that joins the two fragments, whereas for the $\mathrm{B}_{3} \mathrm{H}_{7}$ one, while it is mainly centered on $\mathrm{B}_{1}$ boron atom, the two, $\mathrm{B}_{2}$ and $\mathrm{B}_{3}$, others also are involved through a suitable p orbital. Nevertheless, the donor fragment is not on the $\mathrm{B}_{1} \mathrm{~B}_{2} \mathrm{~B}_{3}$ triangle center (Figure 2).

The donor molecular orbital analysis brings out a weak difference concerning $a^{\prime}$ MOs, which is implied in the stabilizing interaction. This difference has an important consequence on the complexation energy evolution along the column of the periodic table corresponding to the central atom of the donor fragment. In fact, the $\mathrm{NH}_{3}$ donor participates only by the $4 a^{\prime}$ HOMO, whereas $\mathrm{PH}_{3}$ and $\mathrm{AsH}_{3}$ participate by the $n a^{\prime}$ HOMO and $(n-2) a^{\prime}(n=7$ and 13, respectively). This latter MO is so much energetically deeper in the $\mathrm{NH}_{3}$ fragment that it does not affect the $3 \mathrm{MO}-4 \mathrm{e}$ stabilizing mixture of $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{NH}_{3}$ interaction, whereas in the two other compounds, its energy position enables it to intervene in this interaction. Having a perturbational role (destabilizing), these molecular orbitals unfavorably act in the coordination process and have a consequence on the complexation energy evolution despite the similarity of the coordination mode within this series.

Concerning the second interaction, it occurs between the occupied $a^{\prime \prime} \mathrm{MO}$ of both fragments. Having 2MO-4e character,
this interaction is destabilizing and disfavors the coordination (Figure 4). The energetic position of the $\mathrm{XH}_{3}$ donor fragment $a^{\prime \prime}$ molecular orbital becomes closer to those of the acceptor and, consequently, the destabilizing interaction becomes stronger with the series (N, P, and As). Nevertheless, the destabilizing interaction is lower than the first stabilizing one because the complexation is energetically confirmed.

As we have mentioned before, those two mixtures have an influence on the coordination energy variation within the two series of $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}$ and $\mathrm{BH}_{3} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As). In Table 5 , we notice that for $\mathrm{B}_{3} \mathrm{H}_{7}$, as for $\mathrm{BH}_{3}$ acceptor compounds, the complexation energy decreases on going from $\mathrm{NH}_{3}$ to $\mathrm{AsH}_{3}$ adducts. This evolution does not agree with the HOMO of one of the donors, which becomes energetically close to the vacant orbital of the acceptor, which would lead one to believe that the coordination becomes strong in this direction. The destabilizing interaction increases more quickly, within these two sets from $\mathrm{NH}_{3}$ to $\mathrm{AsH}_{3}$, than the stabilizing one. This results therefore in a decreasing and no regular evolution of the complexation energy.

Finally, by analyzing NBO charge evolution (Table 5), we can conclude that generally, there is no correlation between the complexation energy and the charge transfer for the same Lewis acid. Nevertheless, we notice that the increase of the transferred charge contributes to the stability of $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) complexes according to their homologous $\mathrm{BH}_{3} \mathrm{XH}_{3}$, respectively.

## 4. Conclusion

Both $\mathrm{B}_{3} \mathrm{H}_{7}$ and $\mathrm{BH}_{3}$ borane Lewis acid complexes with electron donors such as $\mathrm{XH}_{3}(\mathrm{X}=\mathrm{N}, \mathrm{P}$, and As) depend on two types of interaction (stabilizing and destabilizing). The first one is ensured by the HOMO(donor)-LUMO(acceptor) mixture, which is weakly perturbed by an occupied $a^{\prime}$ molecular orbital intervention of the acceptor, leading to a $3 \mathrm{MO}-4 \mathrm{e}$ system. The latter perturbation acts unfavorably to the coordination. Another occupied $a^{\prime}$ molecular orbital of the donor also acts against the formation of the complex especially in the $\mathrm{PH}_{3}$ and $\mathrm{AsH}_{3}$ cases. With regard to the strongly destabilizing mixture between the occupied $a^{\prime \prime}$ orbitals, it becomes increasingly strong on going from $\mathrm{NH}_{3}$ to $\mathrm{AsH}_{3}$ because the corresponding interacting orbitals become energetically close. The complexation is a result of those four interactions of which the stabilizing one is the prevailing. The decreasing evolution of the complexation energy is due to the increased variation of the destabilizing interactions in comparison with the stabilizing one.

Furthermore, the complexation of $\mathrm{B}_{3} \mathrm{H}_{7}$ is mainly made on the nonequivalent boron atom, and the two others also are
weakly implied, but the acceptor-donor bond is not on the axis of the three boron atom ring. Confirmed by the NBO energetic analysis and NBO charge calculations, the interaction of any hydrogen atoms of both fragments and the lowering of hyperconjugative contribution in $\mathrm{B}_{3} \mathrm{H}_{7}$ fragment are responsible for the symmetry breaking in $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{PH}_{3}$ and $\mathrm{B}_{3} \mathrm{H}_{7} \mathrm{AsH}_{3}$ adducts.
