Received: December 28, 2006; In Final Form: March 29, 2007

Rate coefficients of the reaction $\mathrm{O}\left({ }^{3} \mathrm{P}\right)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ in the temperature range $782-1410 \mathrm{~K}$ were determined using a diaphragmless shock tube. O atoms were generated by photolysis of $\mathrm{SO}_{2}$ at 193 nm with an ArF excimer laser; their concentrations were monitored via atomic resonance absorption. Our data in the range $886-1410 \mathrm{~K}$ are new. Combined with previous measurements at low temperature, rate coefficients determined for the temperature range $297-1410 \mathrm{~K}$ are represented by the following equation: $k(T)=(2.89 \pm 0.09) \times$ $10^{-16} T^{1.62} \exp [-(1210 \pm 90) / T] \mathrm{cm}^{3}$ molecule ${ }^{-1} \mathrm{~s}^{-1}$; listed errors represent one standard deviation in fitting. Theoretical calculations at the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}) / / \mathrm{B} 3 \mathrm{LYP} / 6-311+\mathrm{G}(3 \mathrm{df})$ level predict potential energies of various reaction paths. Rate coefficients are predicted with the canonical variational transition state (CVT) theory with the small curvature tunneling correction (SCT) method. Reaction paths associated with trans and gauche conformations are both identified. Predicted total rate coefficients, $1.60 \times 10^{-22} T^{3.50}$ $\exp (16 / T) \mathrm{cm}^{3}$ molecule ${ }^{-1} \mathrm{~s}^{-1}$ for the range $300-3000 \mathrm{~K}$, agree satisfactorily with experimental observations. The branching ratios of three accessible reaction channels forming $\mathrm{CH}_{3} \mathrm{CHOH}+\mathrm{OH}(1 \mathrm{a}), \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}+$ $\mathrm{OH}(1 \mathrm{~b})$, and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}(1 \mathrm{c})$ are predicted to vary distinctively with temperature. Below 500 K , reaction 1a is the predominant path; the branching ratios of reactions 1 b , c become $\sim 40 \%$ and $\sim 11 \%$, respectively, at 2000 K.

## Introduction

Ethanol $\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)$ is an important and versatile renewable energy source; it may be used as a neat fuel, as an oxygenate additive, as a fuel extender in an internal engine via combustion, ${ }^{1}$ or in a fuel cell via catalytic electrolytic reactions. ${ }^{2}$ Combustion of ethanol fuel might lead to formation of toxic acetaldehyde $\left(\mathrm{CH}_{3} \mathrm{CHO}\right)$; hence detailed modeling of the oxidation processes of ethanol is important. In addition to pyrolysis of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, the reaction

$$
\begin{equation*}
\mathrm{O}\left({ }^{3} \mathrm{P}\right)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} \rightarrow \text { products } \tag{1}
\end{equation*}
$$

is one of the most important processes in combustion of $\mathrm{C}_{2} \mathrm{H}_{5}-$ OH . Rate coefficients of reaction 1 have been determined in the temperature range $297-886 \mathrm{~K}$ by several groups. ${ }^{3-9}$ Experimental conditions, reported rate coefficients near room temperature, and Arrhenius parameters of these studies are listed

[^0]in Table 1 for comparison; the corresponding Arrhenius plots are also shown in Figure 1. Grotheer et al. (designated GNK in Figure 1) employed both discharge-flow and flash photolysis methods to investigate reaction 1 and reported the only measurement of rate coefficient for $T>450 \mathrm{~K}$; rate coefficients in the range $297-886 \mathrm{~K}$ may be fitted with the equation
\[

$$
\begin{equation*}
k_{1}=9.88 \times 10^{-19} T^{2.46} \exp [-(932 / T)] \mathrm{cm}^{3} \text { molecule }^{-1} \mathrm{~s}^{-1} \tag{2}
\end{equation*}
$$

\]

The recommended value in a literature review by Herron employed this expression. ${ }^{10}$ Owens and Roscoe employed discharge-flow technique coupled with either chemiluminescence or mass spectrometry detection to determine $k_{1}$ in the temperature range $301-439 \mathrm{~K}$ and reported ${ }^{6}$

$$
\begin{align*}
k_{1}= & (6.95 \pm 0.85) \times \\
& \left.10^{-13} \exp [-(758 \pm 204) / T)\right] \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{3}
\end{align*}
$$

In a later report, after considering effects from regeneration of ethanol from disproportionation reaction of the $\alpha$-alkanol

A combination of first character of each author's last name is used to indicate previous reports, as listed in Table 1.
radicals, Ayub and Roscoe revised this rate coefficient to become 1.6 times that listed in eq 3 ,

$$
\begin{align*}
k_{1}= & (1.12 \pm 0.13) \times \\
& \left.10^{-12} \exp [-(758 \pm 204) / T)\right] \mathrm{cm}^{3} \text { molecule }^{-1} \mathrm{~s}^{-1} \tag{4}
\end{align*}
$$

as shown in Figure 1 and designated as AR. ${ }^{7}$
Rate coefficients of this reaction show a non-Arrhenius behavior, as prersented in Figure 1 and indicated by eq 2. The rate coefficient is predicted to increase more rapidly at temperatures above 500 K , yielding an upward curved Arrhenius plot. However, even in the low-temperature range 301-439 K, rate coefficient described by eqs 4 and 2 vary by as much as $47 \%$ with activation energies varied from $E / R=758 \pm 204$ to $1800 \pm 60$ K. ${ }^{6,9}$ Experimental data for temperatures above 886 K , critical to combustion, are lacking.

There are three energetically accessible channels for this reaction at high temperature, as the oxygen atom may attack hydrogen atoms at three distinct positions,

$$
\begin{align*}
\mathrm{O}\left({ }^{3} \mathrm{P}\right)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH} & \rightarrow \mathrm{OH}+\mathrm{CH}_{3} \mathrm{CHOH}  \tag{1a}\\
& \rightarrow \mathrm{OH}+\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}  \tag{1b}\\
& \rightarrow \mathrm{OH}+\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O} \tag{1c}
\end{align*}
$$

The branching between these channels plays important roles in the formation of the end products, inhibition of flames, formation of soot, and pollution control. ${ }^{11,12}$ Washida used photoionization spectrometry to show that reaction 1a account for $98-100 \%$ of the total rate of reaction 1 at $300 \mathrm{~K} .{ }^{8}$ Dutton and co-workers employed laser-induced fluorescence under crossed molecular beam conditions to determine the branching ratio for the reaction of $\mathrm{O}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OD}$; they found that reaction 1 c is faster than
reactions 1a,b at a translational temperature of $3500 \mathrm{~K} .{ }^{13}$ Marinov compared existing experimental data with branching ratios of reactions of oxygen atoms with methane and propane to predict the temperature dependence of the rate coefficients to $\mathrm{be}^{12}$

$$
\begin{equation*}
k_{1 \mathrm{a}}=3.12 \times 10^{-17} T^{1.85} \exp [-(918 / T)] \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{5}
\end{equation*}
$$

$k_{1 \mathrm{~b}}=1.56 \times$

$$
\begin{equation*}

\end{equation*}
$$

$k_{1 \mathrm{c}}=2.62 \times$

$$
\begin{equation*}
10^{-17} T^{2.00} \exp [-(2239 / T)] \mathrm{cm}^{3} \text { molecule } \mathrm{e}^{-1} \mathrm{~s}^{-1} \tag{7}
\end{equation*}
$$

According to this model, reaction 1c becomes increasingly important at higher temperatures and reaches a branching ratio similar to that of reaction 1a near 1400 K . By comparison with our previous investigations of the reaction $\mathrm{O}+\mathrm{CH}_{3} \mathrm{OH},{ }^{14}$ the branching ratio of reaction 1 c seems to be greater than expected, especially at low temperatures. To the best of our knowledge, no theoretical investigation on the $\mathrm{O}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ system with high-level quantum-chemical calculations has been reported.

Because of the importance of this reaction in combustion, kinetic data at higher temperatures are needed. We have determined rate coefficients of the title reaction up to 1410 K with a diaphragmless shock tube. We also performed theoretical calculations on this reaction to compare with our experimental measurements and to understand the branching among these three H -abstraction channels at varied temperatures.

## Experiments

All experiments were carried out at NCTU. The diaphragmless shock tube apparatus and technique have been described previously. ${ }^{15,16}$ The shock tube (length 5.9 m and i.d. 7.6 cm ) is coupled with a detection arrangement using atomic resonance absorption. A microwave-discharged lamp with a flowing gas mixture of $\sim 1 \% \mathrm{O}_{2}$ in He served as a light source for spectral absorption of O atoms. Emission at 130.23, 130.49, and 130.60 nm , corresponding to transitions of $\mathrm{O}\left({ }^{3} \mathrm{~S}-{ }^{3} \mathrm{P}_{2,1,0}\right)$, passes perpendicularly through the shock tube near the end before entering into a vacuum UV monochromator (reciprocal linear dispersion $4.0 \mathrm{~nm} \mathrm{~mm}{ }^{-1}$, slit width $350 \mu \mathrm{~m}$ ) before being detected with a solar-blind photomultiplier tube. The speed of the shock wave was determined with four pressure sensors connected to three time-frequency counters for measurements of intervals of arrival signals.

For kinetic measurements, O atoms were generated from $\mathrm{SO}_{2}$ by laser photolysis at 193 nm . At 193 nm , the absorption cross section of $\mathrm{SO}_{2}$ is $3.4 \times 10^{-18} \mathrm{~cm}^{2}$ at 1100 K and $2.8 \times 10^{-18}$ $\mathrm{cm}^{2}$ at $2000 \mathrm{~K} .{ }^{17}$ Light from the ArF excimer laser at 193 nm enters the shock tube from the quartz end-plate and passes along
the tube. A pulse generator was employed to trigger the photolysis laser about $50-150 \mu$ s after the arrival of the incident shock wave detected with the pressure sensor located closest to the end-plate.

Before each experiment, the system was pumped below 5.0 $\times 10^{-7}$ Torr. The temperature $\left(T_{5}\right)$, density $\left(\rho_{5}\right)$, and pressure $\left(P_{5}\right)$ in the reflected shock regime were calculated from measured velocity of the incident shock and the initial pressure, temperature, and composition of the test gas using the ideal shock-wave theory ${ }^{18}$ with Mirels' boundary layer corrections. ${ }^{19,20}$ Because we are interested in the temperature range $780-1400 \mathrm{~K}$, we employed Ne instead of Ar as the buffer gas.

We calibrated the concentration of O atoms in the shock tube with pyrolysis of $\mathrm{N}_{2} \mathrm{O}$ by assuming a $100 \%$ yield of O atoms. ${ }^{21}$ The concentration of O atoms is fitted with the equation
$[\mathrm{O}] / 10^{13}$ molecule $\mathrm{cm}^{-3}=4.499 A-3.208 A^{2}+4.356 A^{3}$
in which absorbance $A=\ln \left(I_{0} / I\right)$ is calculated with the light intensity before and after production of O atoms, denoted as $I_{0}$ and $I$, respectively.

He ( $99.9995 \%$, AGA Specialty Gases), Ne (99.999\%, AGA Specialty Gases), $\mathrm{N}_{2} \mathrm{O}$ ( $99.999 \%$, Scott Specialty Gases), $\mathrm{O}_{2}$ ( $99.995 \%$, Scott Specialty Gases), and $\mathrm{SO}_{2}$ ( $99.98 \%$, Matheson) were used without further purification. $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(99.8 \%$, Mallinckrodt, Analytical Reagent grade) was purified by passing the vapor through $\mathrm{P}_{2} \mathrm{O}_{5}$ to remove trace water impurity. Mixtures of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ in $\mathrm{Ne}(40-442 \mathrm{ppm})$ and $\mathrm{SO}_{2}$ in $\mathrm{Ne}(192-699$ ppm) were used. The concentration of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ in Ne was carefully calibrated with IR absorption in a multipass absorption cell.

## Computational Methods

The geometries of reactants, intermediates, transition states, and products, including gauche- and trans-conformers, of the $\mathrm{O}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ system were optimized at the B3LYP/6-311+G(3df) level of theory. Single-point energies of all species were calculated with the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p})$ method, ${ }^{22}$ based on the optimized geometries.

Rate coefficients for different reaction paths in the temperature range of $T=300-3000 \mathrm{~K}$ were calculated with canonical variational transition state theory (CVT) with zero curvature tunneling corrections (ZCT) and small curvature tunneling corrections (SCT) using the POLYRATE program of Truhlar et al. ${ }^{23}$

All calculations were carried out with Gaussian $03^{24}$ programs using a PC cluster and the computers at the Emerson Computation Center of Emory University.

## Results and Discussion

Thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ at high temperature should be considered before characterizing the title reaction. The decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ not only decreases its concentration but also triggers a series of secondary reactions involving either O atoms or other reactive intermediates. Despite extensive experimental investigations of thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5}$ OH , the branching of each channel remains uncertain. ${ }^{25}$ We rely on theoretical predictions of the branching ratio of pyrolysis in the modeling. ${ }^{26-30}$ According to the prediction, below 10 atm and in the temperature range $700-2500 \mathrm{~K}$, the dominant channel is the formation of $\mathrm{C}_{2} \mathrm{H}_{4}$ and $\mathrm{H}_{2} \mathrm{O}$; at the high-pressure limit and $T>1500 \mathrm{~K}$, formation of $\mathrm{CH}_{3}+\mathrm{CH}_{2} \mathrm{OH}$ becomes

Figure 2. A typical temporal profile of [ O ] observed after irradiation of a sample containing $\mathrm{SO}_{2}(300 \mathrm{ppm})$ and $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(80 \mathrm{ppm})$ in Ar . $T=1135 \mathrm{~K}$, and total density $=1.20 \times 10^{19}$ molecule $\mathrm{cm}^{-3}$. The thick solid line represents fitted results using the model described in text.
dominant and the channel to form $\mathrm{CH}_{3} \mathrm{CH}_{2}+\mathrm{OH}$ also becomes competitive. All experiments were carried out at $T<1450 \mathrm{~K}$ to minimize complications due to thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$.
A. Rate Coefficient $\boldsymbol{k}_{\mathbf{1}}$ for $\mathrm{O}+\mathbf{C}_{2} \mathbf{H}_{\mathbf{5}} \mathbf{O H}$. Experiments were carried out under pseudo-first-order conditions with $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]_{0}$ $\gg[\mathrm{O}]$. Figure 2 shows a typical temporal profile recorded for the mixture containing $\mathrm{SO}_{2}, \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, and Ne after laser photolysis at 193 nm . The concentration of O atoms at reaction period $t,[\mathrm{O}]_{t}$, is derived according to eq $8 .[\mathrm{O}]_{t}$ follows an exponential decay in the initial stage. The apparent pseudo-first-order rate coefficient $k^{1}$ is derived with the equation

$$
\begin{equation*}
\ln \left([\mathrm{O}]_{t} /[\mathrm{O}]_{0}\right)=-k^{\mathrm{I}} t+a t^{2}-b t^{3} \tag{9}
\end{equation*}
$$

in which $a$ and $b$ are fitting parameters to account for small deviation from the exponential decay due to secondary reactions. The apparent bimolecular rate coefficient, $k_{1}^{\prime}$, is thus derived from

$$
\begin{equation*}
k_{1}^{\prime}=k^{\mathrm{I}} /\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]_{0} \tag{10}
\end{equation*}
$$

Comparison of $k_{1}^{\prime}$ with the true bimolecular rate coefficient $k_{1}$ provides information on the extent of interference due to secondary reactions.

At low temperature, previous experiments indicate that reaction 1 is dominated by channel (1a). ${ }^{8}$ Washida used photoionization spectrometry to show that reaction 1a account for $98-100 \%$ of the total rate of reaction 1 at 300 K . However, according to Marinov, ${ }^{12}$ as temperature increases, reaction 1c becomes more important and becomes the most important channel above 1400 K . Our theoretical calculations (discussed in section C) show that reaction 1 c is unimportant under our experimental conditions and the branching ratio of reaction 1 b increases from $\sim 0.15$ at 1000 K to $\sim 0.28$ at 1400 K . Because we are only probing the decay of [O] and cannot distinguish among channels (1a)-(1c) in our experiments, in our model we employed branching ratios calculated theoretically in this work to derive the total decay coefficient. Because of the small branching ratio for reactions $1 \mathrm{~b}, \mathrm{c}$, the errors in these branching ratios do not affect much the value of total rate coefficient.

Photolysis of $\mathrm{SO}_{2}$ at 193 nm is quite efficient in generating O atoms, thus enabling us to use smaller concentrations of $\mathrm{SO}_{2}$. In our previous experiments with $\mathrm{CH}_{3} \mathrm{OH}$, no significant

${ }^{a}$ Key: $P_{1}$, pressure of reactant gas mixture; $P_{4}$, pressure of driver gas; $M_{\mathrm{s}}$, Mach number; $T_{5}$, temperature of reaction. Concentrations are in units of molecule $\mathrm{cm}^{-3}$, $k_{1}$ in $\mathrm{cm}^{3}$ molecule ${ }^{-1} \mathrm{~s}^{-1}$ are fitted with kinetic modeling, and $k_{1}^{\prime}$ are derived from pseudo-first-order decays; see text.
variations in derived rate coefficients were observed for photolysis of $\mathrm{SO}_{2}$ at 193 and 248 nm . The absorption cross section of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ at $193 \mathrm{~nm}, 6.5 \times 10^{-19} \mathrm{~cm}^{2},{ }^{31}$ is similar to that of $\mathrm{CH}_{3} \mathrm{OH}, 3.2 \times 10^{-19} \mathrm{~cm}^{2} ; 32$ hence, the effect of photolysis of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ at 193 nm is small.

Several interference reactions need to be considered. According to modeling, at 1500 K and $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]_{0}=2.66 \times 10^{15}$, $\left[\mathrm{SO}_{2}\right]_{0}=2.74 \times 10^{15}$, and $[\mathrm{Ne}]=1.33 \times 10^{19}$ molecule $\mathrm{cm}^{-3}$, less than $20 \%$ of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ decomposes within $90 \mu$ s; they proceed via the following paths:

$$
\begin{align*}
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(+\mathrm{M}) & \rightarrow \mathrm{C}_{2} \mathrm{H}_{4}+\mathrm{H}_{2} \mathrm{O}(+\mathrm{M})  \tag{11a}\\
& \rightarrow \mathrm{CH}_{2} \mathrm{OH}+\mathrm{CH}_{3}(+\mathrm{M}) \tag{11b}
\end{align*}
$$

The products $\mathrm{CH}_{2} \mathrm{OH}$ and $\mathrm{CH}_{3}$ react rapidly with O atoms

$$
\begin{gather*}
\mathrm{O}+\mathrm{CH}_{2} \mathrm{OH} \rightarrow \mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}  \tag{12}\\
\mathrm{O}+\mathrm{CH}_{3} \rightarrow \mathrm{CH}_{2} \mathrm{O}+\mathrm{H} \tag{13}
\end{gather*}
$$

Hence, subsequent reactions involving H and OH need to be considered. Reactions of O atoms with the major product of reaction 1,

$$
\begin{equation*}
\mathrm{O}+\mathrm{CH}_{3} \mathrm{CHOH} \rightarrow \mathrm{CH}_{3} \mathrm{CHO}+\mathrm{OH} \tag{14}
\end{equation*}
$$

also needs consideration; this reaction is responsible for production of OH in addition to the title reaction.

Because we used $\mathrm{SO}_{2}$ as the source of O atoms, reactions involving $\mathrm{SO}, \mathrm{SO}_{2}$, and $\mathrm{SO}_{3}$ should also be considered: ${ }^{14}$

$$
\begin{gather*}
\mathrm{O}+\mathrm{SO} \rightarrow \mathrm{~S}+\mathrm{O}_{2}  \tag{15a}\\
\mathrm{O}+\mathrm{SO}(+\mathrm{M}) \rightarrow \mathrm{SO}_{2}(+\mathrm{M})  \tag{15b}\\
\mathrm{O}+\mathrm{SO}_{2}(+\mathrm{M}) \rightarrow \mathrm{SO}_{3}(+\mathrm{M})  \tag{16a}\\
\mathrm{O}+\mathrm{SO}_{2} \rightarrow \mathrm{SO}+\mathrm{O}_{2} \tag{16b}
\end{gather*}
$$

We modeled observed temporal profiles of [O] with a commercial kinetic modeling program FACSIMILE. ${ }^{33}$ The reactions employed in the model are listed in Table 2; the program is basically a simplified version of that employed by Marinov ${ }^{12}$ with additional reactions involving S and $\mathrm{SO}_{x}$ and with updated rate coefficients. The rate coefficients are obtained from listed literature unless noted. It should be noted that
inclusion of 57 reactions in the model is only for completeness. If we use a further simplified model with 10 major reactions (marked with an asterisk in Table 2), the results are within 5\% of those derived with a more complete model.

Because the laser was triggered about 50-150 $\mu$ s after arrival of the reflected shock wave at the observation zone, pyrolysis of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ before generation of O atoms should be taken into account, especially at high temperature. We modeled these reactions in two separate periods: the first period started from the arrival of the reflected shock wave and ended with the arrival of the photolysis laser pulse, and the second period started on arrival of the photolysis laser pulse. In the first period, we used $[\mathrm{O}]=0$ to derive concentrations of all reactants and intermediates at the end of this period, which were then employed in the second period, along with experimentally observed concentration of laser-produced O atoms, to model the temporal profile of [O]. In the fitting, the branching ratio of the title reaction was calculated quantum-chemically in this work, literature values of rate coefficients of all reactions in the model except the title reaction $k_{1}$ were held constant, and the bimolecular rate coefficient $k_{1}$ was varied to yield the best fit.

Experimental conditions and values of $k_{1}$ for 71 measurements in a temperature range $782-1410 \mathrm{~K}$ using mixtures of various concentrations of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(40-442 \mathrm{ppm})$ and $\mathrm{SO}_{2}(192-699$ ppm ) are summarized in Table 3. Ranges of reactant concentrations are as follows: $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]_{0}=(0.30-8.15) \times 10^{15}$ molecule $\mathrm{cm}^{-3} ;\left[\mathrm{SO}_{2}\right]_{0}=(1.56-10.3) \times 10^{15}$ molecule $\mathrm{cm}^{-3}$; $[\mathrm{O}]_{0}=(1.40-11.3) \times 10^{13}$ molecule $\mathrm{cm}^{-3} ;[\mathrm{Ne}]=(6.80-$ $22.4) \times 10^{18}$ molecule $\mathrm{cm}^{-3}$. There is no obvious systematic deviation for a specific set of data, supporting that our model is adequate. Values of $k_{1}^{\prime} / k_{1}$, also listed in Table 3, indicate that the pseudo-first-order model in general yields rate coefficient greater by as much as 2.1 times the true value and secondary reactions should be taken into account in these cases. Typically the deviation is smaller when $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right] /[\mathrm{O}]$ and the temperature are greater.

Sensitivity analysis has been performed for representative conditions near 1100,1200 , and 1300 K ; the results are shown in Table 4. The rate coefficient of the title reaction is most sensitive to variations of rate coefficients of reactions 11,25 , 33,35 , and 54 at low temperatures and reactions $11,19,30$, 33, 35, and 54 at high temperatures. In most cases, at temperatures below 1450 K the rate coefficient $k_{1}$ varies by less than $20 \%$ if the rate coefficient of one of the above reactions was varied by a factor of 2 . In the extreme case at temperatures near 1450 K at which pyrolysis of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$

TABLE 4: Sensitivity Factors $\partial \ln [O] / \partial \mathrm{ln} k$ of Important Reactions in the Mechanism for the System $\mathbf{O}+\mathrm{C}_{2} \mathbf{H}_{5} \mathbf{O H}$ under Various Experimental Conditions

becomes more important, we found that rate coefficient $k_{1}$ would increase by as much as $15 \%$ if $k_{11}$ were neglected in the model.

Some representative decay curves covering the whole temperature range of study were also modeled with a complete model consisting of 372 reactions employed by Marinov, ${ }^{12}$ with updated rate coefficients for reactions $2,3,18,19,21,25,29$, $34,46,47,60,107,108,110,130,132,135,137,138,139$, $143,144,145,159,191,193,204$, and 205 in their model, reactions involving sulfur compounds listed as reactions 15 and 16 in this paper, and two additional reactions (reactions 15 and 57 in Table 3) not included in the model of Marinov. ${ }^{12}$ Derived rate coefficients are similar to those listed in Table 3 using our model, with deviations less than $3 \%$.

We tested the effect of branching ratio $k_{1 \mathrm{a}} /\left(k_{1 \mathrm{a}}+k_{1 \mathrm{~b}}+k_{1 \mathrm{c}}\right)$ on derived total rate coefficient $k_{1}$ by using the ratios proposed by Marinov ${ }^{12}$ and found that derived rate coefficient $k_{1}$ varied
by at most $5 \%$. We also tested the effect of thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ before its reaction with O atoms. Thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ has two effects: the decrease in $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]$ and effects due to secondary reactions involving pyrolysis products $\mathrm{CH}_{3}$ and $\mathrm{CH}_{2} \mathrm{OH}$. When we took out the simulation of the first period (i.e., to assume that thermal decomposition of $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ was negligible before the photolysis laser arrived), we found that fitted rate coefficients $k_{1}$ increased by $<1 \%$ for reaction temperatures below 1200 K , indicating that the small decrease in $\left[\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]$ during the first period was negligible. In contrast, we found that $k_{1}$ increased by $<5 \%$ for temperatures at 1410 K because $6 \% \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ dissociated in the first period.
Calculated branching ratios of thermal decomposition of ethanol, R19 and R20 in Table 2, in the literature have large discrepancies. The rate coefficients of R19 predicted by Li et al. ${ }^{34}$ are smaller by factors of 0.75 and 0.40 at 1400 and 1000

Figure 3. Comparison of experimental total rate coefficient $k_{1}$ with theoretical calculations: medium dash line, CVT with SCT tunneling correction; dotted line, CVT; O, this work; $\mathbf{\Delta}, \mathrm{GNK} ;{ }^{9} \nabla, \mathrm{AR} ;{ }^{7} \bigcirc \mathrm{KC} ;{ }^{3} ■$, Washida. ${ }^{8}$ Inset: Expanded view of data from this work. $\mathrm{Key:} \mathrm{O}, \mathrm{SO}(300 \mathrm{ppm})$ $+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(80 \mathrm{ppm}) ; \square, \mathrm{SO}_{2}(502 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(80 \mathrm{ppm}) ; \times, \mathrm{SO}_{2}(206 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(164 \mathrm{ppm}) ;$, $\mathrm{SO}_{2}(333 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(81 \mathrm{ppm}) ;$ $\square, \mathrm{SO}_{2}(214 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(81 \mathrm{ppm}) ; \square, \mathrm{SO}_{2}(192 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(442 \mathrm{ppm}) ; \square, \mathrm{SO}_{2}(302 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(164 \mathrm{ppm}) ; \square, \mathrm{SO}_{2}(206 \mathrm{ppm})$ $+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(40 \mathrm{ppm}) ; \square, \mathrm{SO}_{2}(504 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(165 \mathrm{ppm}) ;-\mathrm{SO}_{2}(699 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(80 \mathrm{ppm}) ; \Delta, \mathrm{SO}_{2}(404 \mathrm{ppm})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(40 \mathrm{ppm}) ;$ ©, GNK. ${ }^{9}$

Figure 4. Geometries of reactant $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$, transition states, and products of the $\mathrm{O}+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ system optimized at the B3LYP/6$311+G(3 \mathrm{df})$ level. Listed bond lengths are in $\AA$, and bond angles are in deg. 2OI indicates that two optical isomers exist for this configuration.

K, respectively, than those predicted by Park et al. ${ }^{28}$ In contrast, rate coefficients of R20 predicted by Li et al. ${ }^{34}$ are greater by factors of 4.8 at 1400 K and 2.9 at 1000 K than those predicted by Park et al. ${ }^{28}$ We employed these rate coefficients reported by Li et al. in our model and derived rate coefficients of the title reaction $k_{1}$ smaller by $<6 \%$ than those using the smaller values of Park et al.; the largest deviation was observed at higher temperatures and with greater concentration of $\mathrm{SO}_{2}$.

Values of $k_{1}$ are compared with previous reports in Figure 3; an expanded view is shown in the inset. Fitting our results to an Arrhenius equation yields

$$
\begin{align*}
k_{1}= & (1.34 \pm 0.11) \times \\
& 10^{-10} \exp [-(3040 \pm 80) / T] \mathrm{cm}^{3} \text { molecule }^{-1} \mathrm{~s}^{-1} \tag{17}
\end{align*}
$$

for $782<T / \mathrm{K}<1410$, in which listed errors represent one standard deviation in fitting, unless otherwise noted. Observed value of $E_{\mathrm{a}} / R=3040 \mathrm{~K}$ is much greater than the value $E_{\mathrm{a}} / R=$ 758 K reported previously from measurements at temperatures $301-439 \mathrm{~K},{ }^{6,7}$ indicating clearly the non-Arrhenius temperature dependence with an upward curvature. Our rate coefficients are smaller by $23-28 \%$ than those reported by Grotheer et al. in the overlapped range of temperature 782-886 K; ${ }^{9}$ the deviations are within experimental error limits. Our work extends the temperature range of study from 886 to 1410 K. Fitting combined data for this work and those of Grotheer et al. yields

$$
\begin{align*}
& k_{1}=(2.89 \pm 0.09) \times \\
& \quad 10^{-16} T^{1.62} \exp [-(1210 \pm 90) / T] \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{18}
\end{align*}
$$

B. Potential Energy Surfaces and Reaction Mechanism. As shown in Figure 4, the $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ has trans (dihedral angle $\left.\phi(\mathrm{HOCC})=180.0^{\circ}\right)$ and gauche (dihedral angle $\phi(\mathrm{HOCC})=$ $60.3^{\circ}$ ) conformers. They can transform to each other via a transition state $t-g-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}-\mathrm{TS}$ with a small barrier of 0.7 kcal $\mathrm{mol}^{-1}$. The oxygen atom reacts with both conformers. The potential energy diagram obtained by single-point $\operatorname{CCSD}(\mathrm{T}) /$ $6-311+G(3 \mathrm{df}, 2 \mathrm{p})$ calculations on the basis of geometries optimized at the B3LYP/6-311+G(3df) level is presented in Figure 5. Total energies of the reactants and relative energies of the transition states and products are listed in Table 5. Vibrational wavenumbers and moments of inertia of all species are summarized in Table 6.

The oxygen atom may attack $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ at one of the two hydrogen atoms of the $\mathrm{CH}_{2}$ group (reaction 1a), one of the three hydrogen atoms of the $\mathrm{CH}_{3}$ group (reaction 1 b ), or the H atom of the hydroxyl group (reaction 1c). As shown in Figure 5, the trans path of reaction 1a proceeds via trans- $\mathrm{TS}_{1}$ (dihedral angle $\left.\phi(\mathrm{HOCC})=174.0^{\circ}\right)$ with a barrier of $4.2 \mathrm{kcal} \mathrm{mol}^{-1}$ and forms trans $-\mathrm{CH}_{3} \mathrm{CHOH}$ and OH with energy $-6.6 \mathrm{kcal} \mathrm{mol}^{-1}$ relative to that of the reactants. The corresponding gauche path has a barrier of $4.3 \mathrm{kcal} \mathrm{mol}{ }^{-1}$ via gauche- $\mathrm{TS}_{1}$ (dihedral angle $\phi$ -$\left.(\mathrm{HOCC})=-40.6^{\circ}\right)$ and $\Delta H$ of $-6.3 \mathrm{kcal} \mathrm{mol}^{-1}$ for formation of cis- $\mathrm{CH}_{3} \mathrm{CHOH}$.

The trans path for reaction 1 b proceeds via the trans- $\mathrm{TS}_{2 \mathrm{a}}$ $\left(\right.$ dihedral angle $\left.\phi(\mathrm{HOCC})=-174.0^{\circ}, \phi(\mathrm{OCCO})=71.9^{\circ}\right)$ with a barrier of $9.3 \mathrm{kcal} \mathrm{mol}^{-1}$ or the trans- $\mathrm{TS}_{2 \mathrm{~b}}$ (dihedral angle $\left.\phi(\mathrm{HOCC})=\phi(\mathrm{OCCO})=180.0^{\circ}\right)$ with a barrier of 9.8 kcal $\mathrm{mol}^{-1}$ to form trans $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ and OH with $\Delta H=0.7 \mathrm{kcal}$ $\mathrm{mol}^{-1}$. The corresponding gauche path for reaction 1 b proceeds via gauche $-\mathrm{TS}_{2 \mathrm{a}}\left(\right.$ dihedral angle $\phi(\mathrm{HOCC})=-58.2^{\circ}, \phi(\mathrm{OCCO})$ $=56.0^{\circ}$ ) with a barrier of $7.7 \mathrm{kcal} \mathrm{mol}^{-1}$ or gauche $-\mathrm{TS}_{2 \mathrm{~b}}$ $\left(\right.$ dihedral angle $\left.\phi(\mathrm{HOCC})=68.6^{\circ}, \phi(\mathrm{OCCO})=-175.7^{\circ}\right)$ with a barrier of $9.7 \mathrm{kcal} \mathrm{mol}^{-1}$ to form gauche $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ and OH with $\Delta H=0.3 \mathrm{kcal} \mathrm{mol}^{-1}$.

The trans path of reaction 1c proceeds via trans- $\mathrm{TS}_{3}$ (dihedral angle $\left.\phi(\mathrm{HOCC})=180.0^{\circ}\right)$ with a barrier of $10.7 \mathrm{kcal} \mathrm{mol}^{-1}$ and forms $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}$ and OH with $\Delta H=2.1 \mathrm{kcal} \mathrm{mol}{ }^{-1}$. The corresponding gauche path proceeds via gauche- $\mathrm{TS}_{3}$ (dihedral angle $\left.\phi(\mathrm{HOCC})=64.7^{\circ}\right)$ with a barrier of $10.0 \mathrm{kcal} \mathrm{mol}^{-1}$.

The predicted enthalpies of reaction for the three branching reactions are compared with experimental values in Table 5. The predicted enthalpy changes for reactions $1 \mathrm{a}-\mathrm{c}$ at $0 \mathrm{~K},-6.5$ $\pm 0.2,0.5 \pm 0.2$, and $2.1 \mathrm{kcal} \mathrm{mol}^{-1}$, are close to the experimental values $-8.7 \pm 0.2,2.3 \pm 0.2$, and $1.7 \pm 1.2 \mathrm{kcal}$ $\mathrm{mol}^{-1}$, respectively, on the basis of $\Delta H_{\mathrm{f}, 0}(\mathrm{O})=58.99 \pm 0.02,{ }^{35}$ $\Delta H_{\mathrm{f}, 0}\left(\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right)=-51.88 \pm 0.12,{ }^{35} \Delta H_{\mathrm{f}, 0}\left(\mathrm{CH}_{3} \mathrm{CHOH}\right)=$ $-10.5,{ }^{36} \Delta H_{\mathrm{f}, 0}\left(\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}\right)=-0.05 \pm 0.96,{ }^{35}$ and $\Delta H_{\mathrm{f}, 0}(\mathrm{OH})$ $=8.87 \pm 0.07 \mathrm{kcal} \mathrm{mol}^{-1.35} \Delta H_{\mathrm{f}, 0}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)=0.57 \mathrm{kcal}$ $\mathrm{mol}^{-1}$ is derived from $\Delta H_{\mathrm{f}, 298}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}\right)=-2.46 \mathrm{kcal}$ mol $^{-1} .{ }^{37}$

As shown in Figure 4, the reacting atoms $\mathrm{O}, \mathrm{H}$, and C in trans- $\mathrm{TS}_{1}$ are almost linear, with $\angle \mathrm{OHC}=177^{\circ}$; the length of the breaking $\mathrm{C}-\mathrm{H}$ bond increases by $0.11 \AA$ from that of trans$\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$. The imaginary vibrational wavenumber of trans- $\mathrm{TS}_{1}$ is $355 \mathrm{i} \mathrm{cm}^{-1}$. For gauche $-\mathrm{TS}_{1}, \angle \mathrm{OHC}=176^{\circ}$ and the $\mathrm{C}-\mathrm{H}$ bond length increases by $0.12 \AA$ from that of gauche $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$. The imaginary vibrational wavenumber of gauche- $\mathrm{TS}_{1}$ is 505 i $\mathrm{cm}^{-1}$. For trans $-\mathrm{TS}_{2 \mathrm{a}}$ and trans $-\mathrm{TS}_{2 \mathrm{~b}}, \angle \mathrm{OHC}=177-8^{\circ}$ and the $\mathrm{C}-\mathrm{H}$ bond length increases by $0.22-0.23 \AA$ from that of trans $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$; the imaginary vibrational wavenumbers are

Figure 5. | gauche- $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 46.8, 182.9, 210.7 | $177,329,423,537,827,950,1082,1121,1184,1359,1398,1452,1481,2974,2992,3142,3247,3800$ |
| $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}$ | 45.1, 188.8, 211.8 | 46, 256, 435, 860, 886, 1070, 1097, 1239, 1327, 1389, 1408, 1485, 1493, 2882, 2893, 3031, 3096, 3106 |

1487 i and $1504 \mathrm{i} \mathrm{cm}{ }^{-1}$, respectively. For gauche $-\mathrm{TS}_{2 \mathrm{a}}$ and gauche $-\mathrm{TS}_{2 \mathrm{~b}}$ with $\angle \mathrm{OHC}=168$ and $180^{\circ}$, respectively, the $\mathrm{C}-\mathrm{H}$ bond length increases by 0.21 and $0.20 \AA$ from that of trans $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ and the imaginary vibrational wavenumbers are 1412 i and $1486 \mathrm{i} \mathrm{cm}^{-1}$, respectively. For trans- $\mathrm{TS}_{3}$ and gauche$\mathrm{TS}_{3}, \angle \mathrm{OHO}=161-162^{\circ}$ and the $\mathrm{C}-\mathrm{H}$ bond length increases by $0.17 \AA$ from the corresponding $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ conformer; the imaginary vibrational wavenumbers are 1536 i and $1512 \mathrm{icm}^{-1}$,
respectively. The geometry parameters and imaginary frequencies of the trans and gauche transition states are similar. The trans and gauche transition states can be transformed to each other by the internal rotation about the $\mathrm{C}-\mathrm{O}$ single bond. The trans or gauche $\mathrm{TS}_{2 \mathrm{a}}$ and $\mathrm{TS}_{2 \mathrm{~b}}$ can be transformed to each other by the internal rotation about the $\mathrm{C}-\mathrm{C}$ bond.
C. Calculations and Comparison of Rate Coefficients. As shown in Figure 5, the three direct H -abstraction reaction

Figure 6. Branching ratios for reactions $1 \mathrm{a}-\mathrm{c}$ : solid line, this work; dotted line, Marinov. ${ }^{12}$
channels have barriers of $4.2-10.7 \mathrm{kcal} \mathrm{mol}^{-1}$; hence, tunneling effects for these channels should be considered. Rate coefficients for the three channels in the temperature range $300-3000 \mathrm{~K}$ have been computed with the CVT and the CVT/SCT methods on the basis of the geometries, vibrational frequencies, and rotational constants calculated at the B3LYP/6-311+G(3df) level and the energies calculated at the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}) / /$ B3LYP/6-311+G(3df) level. Because there are two optical isomers for trans- $\mathrm{TS}_{1}$, gauche- $\mathrm{TS}_{1}$, trans- $\mathrm{TS}_{2 \mathrm{a}}$, gauche $-\mathrm{TS}_{2 \mathrm{a}}$, gauche $-\mathrm{TS}_{2 \mathrm{~b}}$, and gauche $-\mathrm{TS}_{3}$, a statistical factor of 2 is employed in the calculations.

Because of the existence of the trans $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ and gauche$\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ conformers and their corresponding transition states, the rate coefficient for the reaction of each conformer should be taken into account using their equilibrium concentrations at each temperature. The thermal equilibrium constant, $K=$ [gauche $\left.-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right] /\left[\right.$ trans $\left.-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}\right]=0.87-0.97$ in the temperature range $300-3000 \mathrm{~K}$, can be calculated with the Chemrate Program. ${ }^{38}$ The predicted rate coefficients for channels (1a), (1b), and (1c) are derived from rate coefficients of the trans $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ and gauche $-\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ reactions: ${ }^{39}$

$$
\begin{align*}
& k_{1 \mathrm{a}}(T)=\left(k_{\text {trans-1a }}(T)+k_{\text {gauche }-1 \mathrm{a}}(T) K\right) /(1+K)  \tag{19}\\
& k_{1 \mathrm{~b}}(T)=\left(k_{\text {trans-1b }}(T)+k_{\text {gauche }-1 \mathrm{~b}}(T) K\right) /(1+K)  \tag{20}\\
& k_{1 \mathrm{c}}(T)=\left(k_{\text {trans-1b }}(T)+k_{\text {gauche }-1 \mathrm{~b}}(T) K\right) /(1+K) \tag{21}
\end{align*}
$$

In calculations of rate coefficients, the internal rotation about the $\mathrm{C}-\mathrm{O}$ bond in trans- $\mathrm{TS}_{1}, \mathrm{TS}_{2 \mathrm{a}}$, and $\mathrm{TS}_{2 \mathrm{~b}}$ have been treated as hindered rotors. Such treatments increase the total rate coefficient by $59-17 \%$ in the temperature range $300-3000 \mathrm{~K}$.

To compare predicted rate coefficients with experimental data quantitatively, we fit rate coefficients predicted with CVT/SCT for channels (1a), (1b), and (1c) in the temperature range 3003000 K to the three-parameter form to yield

$$
\begin{align*}
k_{1 \mathrm{a}}(T) & = \\
2.41 & \times 10^{-19} T^{2.47} \exp (-441 / T) \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1}  \tag{22}\\
k_{1 \mathrm{~b}}(T) & = \\
1.61 & \times 10^{-21} T^{3.23} \exp (-2344 / T) \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1}  \tag{23}\\
k_{1 \mathrm{c}}(T) & = \\
2.43 & \times 10^{-27} T^{4.73} \exp (-869 / T) \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{24}
\end{align*}
$$

The total rate coefficients calculated with the CVT and CVT/ SCT methods for the temperature range $300-3000 \mathrm{~K}$ are represented as

$$
\begin{align*}
& k_{1}(T)= \\
& 3.77 \times 10^{-20} T^{2.86} \exp [-(1265 / T)] \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{25}
\end{align*}
$$

and

$$
\begin{equation*}
k_{1}(T)=1.60 \times 10^{-22} T^{3.50} \exp (16 / T) \mathrm{cm}^{3} \text { molecule }{ }^{-1} \mathrm{~s}^{-1} \tag{26}
\end{equation*}
$$

respectively. At 300 K , rate coefficients of reactions $1 \mathrm{a}-\mathrm{c}$ predicted with CVT/SCT are 10, 58, and 1330 times those predicted with CVT, respectively, resulting to a difference in total rate coefficient of about a factor of 10 . The total rate coefficients calculated with CVT (dotted line) and CVT/SCT (medium dash line) are plotted in Figure 3 to compare with experimental data of GNK, ${ }^{9} \mathrm{AR},{ }^{7} \mathrm{KC},{ }^{3}$ Washida, ${ }^{8}$ and this work. In general, rates predicted with CVT/SCT are in satisfactory agreement with experimental values, indicating the SCT method treats tunneling effects adequately. At low temperatures, rate coefficients predicted with CVT/SCT are slightly greater than experimental values of $\mathrm{GNK}^{9}$ but within uncertainties of other experiments. An expanded plot for high temperatures is shown in the inset of Figure 3. At high temperatures, predicted rate coefficients fit satisfactorily with experimental data of this work but slightly smaller than those of GNK. ${ }^{9}$ The uncertainty of the barriers of transition states has significant effect on the rate coefficient at low temperatures. The uncertainty of the calculated barriers of transition states is estimated to be $\pm 0.5 \mathrm{kcal} \mathrm{mol}^{-1}$ due to errors in accuracy of computations and treatment of hindered rotors and tunneling corrections. The predicted total rate coefficients increase to $2.4-1.1$ times the original value in the temperature range $300-3000 \mathrm{~K}$ when the calculated barriers of transition states decrease by $0.5 \mathrm{kcal} \mathrm{mol}^{-1}$; they decrease to $0.4-0.9$ times when the calculated barriers increase by 0.5 $\mathrm{kcal} \mathrm{mol}^{-1}$. The uncertainties are shown as shaded region in Figure 3; they cover the uncertainty range of the experimental data in the whole temperature range.

The branching ratios of channels (1a), (1b), and (1c) predicted with the CVT/SCT method for $T=300-3000 \mathrm{~K}$ are plotted in Figure 6. Reaction 1a is the predominant channel for $T<500$ K ; its branching ratio decreases from 1.00 at 300 K to 0.81 at 1000 K and 0.31 at 3000 K . The branching ratio for reaction 1 b is 0.03 at 600 K and increases to 0.15 at 1000 K and 0.49 at 3000 K . The branching ratio for reaction 1 c is 0.03 at 1000 K and 0.20 at 3000 K . The branching ratios employed by Marinov are also compared in Figure 6 (dotted lines); ${ }^{12}$ branching ratios of $k_{1 \mathrm{a}}$ appear to be underestimated whereas those of $k_{1 \mathrm{c}}$ are greatly overestimated throughout the temperature range $300-3000 \mathrm{~K}$.

It should be noted that Marinov reported that reaction 1c is more important than reaction 1 b and becomes the most important channel at $T>1400 \mathrm{~K}$, but we predicted reaction lb to be the most important. On the basis of the PES of channels (1a), (1b), and (1c), the barriers of trans- and gauche- $\mathrm{TS}_{3}$ are greater than those of trans- and gauche- $\mathrm{TS}_{2 \mathrm{a}}$ and $\mathrm{TS}_{2 \mathrm{~b}}$, so it is unlikely that the rate coefficients of reaction 1c are greater than those of reaction 1 b , especially at low temperatures. The revised branching ratios for production of $\mathrm{CH}_{3} \mathrm{CHOH}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$, and $\mathrm{CH}_{3}-$ $\mathrm{CH}_{2} \mathrm{O}$ should have significant impacts on the chemical modeling of combustion systems involving ethanol, particularly at high temperatures.

## Conclusion

Total rate coefficients of the reaction $\mathrm{O}\left({ }^{3} \mathrm{P}\right)+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ in the temperature range $782-1410 \mathrm{~K}$ were determined using a
diaphragmless shock tube with atomic resonance absorption detection of O atoms. Our results extended the upper limit of the temperature range of study from 886 to 1410 K and clearly indicated a non-Arrhenius behavior of the rate coefficient. Rate coefficients obtained in this work is slightly smaller than those determined previously by Grotheer et al. ${ }^{9}$ in the overlapped temperature region 782-886 K but within experimental errors. Theoretical calculations at the $\operatorname{CCSD}(\mathrm{T}) / 6-311+\mathrm{G}(3 \mathrm{df}, 2 \mathrm{p}) / /$ B3LYP/6-311+G(3df) level predict transition states and barriers for various channels. Rate coefficients predicted with CVT/SCT show that branching ratios of three accessible reaction channels to form $\mathrm{CH}_{3} \mathrm{CHOH}+\mathrm{OH}(1 \mathrm{a}), \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}+\mathrm{OH}(1 b)$, and $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{O}+\mathrm{OH}(1 \mathrm{c})$ varies with temperature. At $T<600 \mathrm{~K}$, reaction 1a dominates by $>96 \%$, whereas, above 2300 K , reaction 1 b becomes more important with a branching ratio $>44 \%$. The branching for the channel (1c) is less than $12 \%$ for $T<2000$ K. Predicted total rate coefficients are in satisfactory agreement with our experimental data at high temperature (7821410 K ) and those reported previously.

[^1]:    ${ }^{a} k_{0}$ and $k_{\infty}$ refer to low- and high-pressure limits, respectively. The $F_{\mathrm{c}}$ parameters in the Troe equation are listed separately. Unless otherwise noted, all species are assumed to have a third body efficiency of $1.0 .{ }^{b} F_{c}=(1-0.619) \exp [-(T / 73.2)]+0.619 \exp [-(T / 1180)]$. Enhanced third body coefficient (relative to $\left.\mathrm{N}_{2}\right): \eta_{\mathrm{Ar}}=0.7 .{ }^{c} F_{\mathrm{c}}=(1-0.783) \exp [-(T / 74)]+0.783 \exp [-(T / 2941)]+\exp [-(6964 / T)]$. Enhanced third body coefficient (relative to $\mathrm{N}_{2}$ ): $\eta_{\mathrm{Ar}}=0.7 .{ }^{d} F_{\mathrm{c}}=(1-0.025) \exp \left[-\left(T / 1 \times 10^{-15}\right)\right]+0.025 \exp [-(T / 8000)]+\exp [-(3000 / T)]$. Enhanced third body coefficient: $\eta_{\mathrm{H}_{2} \mathrm{O}}=10.0 ; \eta_{\mathrm{H}_{2}}=2.0 ; \eta_{\mathrm{CO}_{2}}=3.0 ; \eta_{\mathrm{CO}}=2.0 .{ }^{e} F_{\mathrm{c}}=\exp [-(T / 95)]+\exp [-(200 / T)]$. Enhanced third body coefficient: $\eta_{\mathrm{H}_{2} \mathrm{O}}=5.0$; $\eta_{\mathrm{H}_{2}}=2.0 ; \eta_{\mathrm{CO}_{2}}=3.0 ; \eta_{\mathrm{CO}}=2.0 .{ }^{f} F_{\mathrm{c}}=(1-0.96) \exp [-(T / 67.6)]+0.96 \exp [-(T / 1855)]+\exp [-(7543 / T)]$.
