# Theoretical Prediction of the $S_{1}-S_{0}$ Internal Conversion of 6-Cyanoazulene 

Yoshiaki Amatatsu*<br>Faculty of Engineering and Resource Science, Akita University, Tegata Gakuen-cho, Akita 010-8502, Japan<br>Received: February 8, 2007; In Final Form: April 12, 2007

#### Abstract

Ab initio complete active-space self-consistent field (CASSCF) and second-order Multireference MöllerPlesset perturbation (MRMP2) calculations were performed to examine the $S_{1}-S_{0}$ internal conversion of 6-cyanoazulene (6CNAZ). The azulene skeletons of 6CNAZ in $S_{0}$ and $S_{1}$ have features that resemble those of azulene. The stable geometry in $\mathrm{S}_{0}$ is characterized by (i) a $C_{2 v}$ structure, (ii) an aromatic bond-equalized structure in which all the peripheral skeletal bond distances resemble an aromatic CC bond distance, and (iii) a single bond character of the transannular bond. The stable geometry in $S_{1}$ is characterized by a nonaromatic $C_{2 v}$ structure. Contrary to similarities of the stable geometries in $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ between 6 CNAZ and azulene, the conical intersection ( $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX) of 6CNAZ is different from that of azulene. The $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of 6 CNAZ takes a planar structure, whereas that of azulene takes a nonplanar structure in the seven-membered ring (Amatatsu, Y.; Komura, K. J. Chem. Phys. 2006, 125, 174311/1-8). On the basis of those computational findings, we predict the photochemical behavior of 6 CNAZ in the $\mathrm{S}_{1}-\mathrm{S}_{0}$ internal conversion.

## 1. Introduction

Azulene is well-known as a molecule that violates Kasha's rule: it is fluorescent from $S_{2}$, but substantially nonfluorescent from $S_{1}$. Since the first discovery of violation of Kasha's rule in $1955,{ }^{1}$ many experimental and theoretical approaches have been undertaken to clarify the abnormal photochemical behavior of azulene. ${ }^{2}$ Nevertheless, a realistic picture of the $S_{1}-S_{0}$ internal conversion (IC) of azulene has not been presented because of a lack of information on the conical intersection (denoted by $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX hereafter), where the radiationless $\mathrm{S}_{1}-\mathrm{S}_{0}$ transition takes place. In 1996, Bearpark et al. first reported the $S_{1} / S_{0^{-}}$ CIX geometry to discuss the IC process. ${ }^{3}$ Their $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX is characterized by the following: (i) it takes a planar structure with $C_{2 v}$ symmetry substantially, (ii) the bond-equalized structure in the peripheral CC skeleton, which is characteristic in $\mathrm{S}_{0}$, disappears, and (iii) the transannular bond shrinks from a normal $\mathrm{C}-\mathrm{C}$ single into a normal $\mathrm{C}=\mathrm{C}$ double bond.

During the past decade, however, several new experimental findings have been reported:
(EXP1) The decay time of azulene in $S_{1}$ depends on excess energy in the electronic excitation of $\mathrm{S}_{0}-\mathrm{S}_{1}: 1.7 \mathrm{ps}$ for the vibrationless $\mathrm{S}_{1}$ state and 0.4 ps for the excess energy of 1300 $\mathrm{cm}^{-1}$ above the $\mathrm{S}_{1}$ electronic origin. ${ }^{4}$ Similar results have been reported from other experiments. ${ }^{5-9}$
(EXP2) $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX is responsible for the ultrafast decay located $2000-2300 \mathrm{~cm}^{-1}$ above the $S_{1}$ electronic origin. ${ }^{4,7,8}$
(EXP3) Strong oscillatory signals attributable to low-frequency out-of-plane vibrations are observed before the decay, ${ }^{4}$ although the contribution of the out-of-plane motion to the IC process has been indicated by other authors. ${ }^{6-8}$

Particularly EXP3 above seems to be beyond the theoretical description of Bearpark et al.: a new model is required. We reported a new conceptualization of $\mathrm{S}_{1}-\mathrm{S}_{0}$ IC of azulene, which enables us to explain the new experimental findings mentioned above. ${ }^{10}$ The most important point among our computational

[^0]findings is that $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX takes a nonplanar structure in the seven-membered ring related to the strong oscillations because of the out-of-plane low-frequency modes in the decay process of azulene in $S_{1}$.

To the best of our knowledge, however, no further experimental or computational findings support nonplanar $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIXs of azulene or its derivatives. For that reason, we theoretically examined the effect on the $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of 6-cyanoazulene (6CNAZ) to compare the $S_{1}-S_{0}$ IC of 6CNAZ with that of the parent azulene.

This paper is organized as follows. In the next section, we describe the calculation method. In section 3, we explain the electronic and geometrical structures of 6CNAZ at important conformations. Based on computational findings, we predict $\mathrm{S}_{1}-\mathrm{S}_{0}$ IC of 6 CNAZ in comparison with that of azulene.

## 2. Method of Calculation

Complete active space self-consistent-field (CASSCF) calculations with 14 electrons in 14 orbitals (denoted as $(14,14)$ CASSCF) are desirable for quantitative discussion of the excited states of 6CNAZ because 6 CNAZ has $14 \pi$ electrons that are originated from the azulene skeleton ( $10 \pi$ electrons) and the cyano group ( $4 \pi$ electrons). However, $(14,14)$ CASSCF calculations are unrealistic to scan the potential energy surfaces for the $S_{1}-S_{0}$ IC of 6CNAZ. Consequently, to reduce the computational load, as we did for another system, diphenylacetylene, ${ }^{11}$ we selected important $\pi$ and $\pi^{*}$ orbitals from all seven occupied $\pi$ and the lowest seven $\pi^{*}$ unoccupied orbitals to perform the configuration interaction (CI) method, where up to triple excitations from the closed-shell configuration are included (i.e., SDT-CI). Results showed that the occupation numbers of the lowest two $\pi$ orbitals and those of the highest two $\pi^{*}$ orbitals are respectively greater than 1.98 and less than 0.02 , for all sampled conformations. Those results imply that the highest five $\pi$ orbitals and the lowest five $\pi^{*}$ orbitals are sufficient to describe $S_{0}$ and $S_{1}$ in our present interest. Therefore, we adopted $(10,10)$ CASSCF method for the scan of the potential energy surfaces. At several conformations, we made corrections for

Figure 1. Numberings of atoms and definition of the coordinates of 6CNAZ. The $y$-axis is perpendicular to the $x z$-plane.
$(10,10)$ CASSCF energy of each electronic state using secondorder multireference Möller-Plesset perturbation (MRMP2). All valence and virtual orbitals were included in perturbation calculations. For this calculation, we imposed the constraint of $C_{s}$ symmetry, as in the calculation of azulene ${ }^{10}$ (see Figure 1). In other words, a planar structure of 6CNAZ is designed to have $C_{2 v}$ symmetry, but a nonplanar structure is allowed under the constraint of $C_{s}$ symmetry. Appendix 1 is a detailed description of why the symmetry constraint was imposed.

First, we optimized the geometries in $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ for 6CNAZ (represented respectively as $\mathrm{S}_{0}$-geometry and $\mathrm{S}_{1}$-geometry). Then we optimized the conical intersection between $S_{1}$ and $S_{0}\left(S_{1} /\right.$ $\mathrm{S}_{0}$-CIX), where the radiationless relaxation takes place. To reduce computational labor in the optimization of $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, we preformed a smaller $(8,8)$ CASSCF calculation based on the preliminary CI result: at most, four occupied and four unoccupied $\pi$-type orbitals are sufficient to describe both $\mathrm{S}_{0}$ and $\mathrm{S}_{1}$ for the region where $S_{0}$ and $S_{1}$ are energetically similar. However, after optimization of $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX by $(8,8)$ CASSCF, we performed a $(10,10)$ CASSCF calculation at $S_{1} / S_{0}$-CIX and verified that the energy difference between $S_{1}$ and $S_{0}$ is sufficiently small to be a CIX. That fact implies that a much more computationally demanding $(10,10)$ CASSCF gives an $\mathrm{S}_{1} /$ $\mathrm{S}_{0}$-CIX similar to that by $(8,8)$ CASSCF .

Electronically excited 6CNAZ at $\mathrm{S}_{0}$-geometry travels into $\mathrm{S}_{1} /$ $S_{0}$-CIX in $S_{1}$ and then relaxes from $S_{1} / S_{0}$-CIX in $S_{0}$. One approach to investigate that phenomenon is to calculate the intrinsic reaction coordinate, as done previously in the case of the $S_{1}-S_{0}$ IC of azulene. ${ }^{10}$ However, because the calculation of the intrinsic reaction coordinate is computationally demanding, we did three types of geometry optimization: (i) $\mathrm{S}_{1^{-}}$ geometry optimization starting from $\mathrm{S}_{0}$-geometry, (ii) that from $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, and (iii) $\mathrm{S}_{0}$-geometry optimization from $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. Therefore, the geometries by optimizations i and ii become $\mathrm{S}_{1^{-}}$ geometry and the geometry by optimization iii become $S_{0^{-}}$ geometry. Consequently, the reaction path is connected successively with three important conformations mentioned above. That is, after electronic excitation into $S_{1}$ at $S_{0}$-geometry, electronically excited 6CNAZ passes through $\mathrm{S}_{1}$-geometry and reaches $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. Then the non-adiabatic transition into $\mathrm{S}_{0}$ takes place at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX and finally reverts to $\mathrm{S}_{0}$-geometry.

Except for the optimization of $S_{1} / S_{0}$-CIX by Gaussian $03,{ }^{12}$ we used the GAMESS program. ${ }^{13}$ The basis set is HuzinagaDunning double- $\zeta$ (DZ) quality; polarization functions are added on the carbon atoms $\left(\alpha_{d}=0.75\right)$ for the azulene skeleton and the nitrogen atom ( $\alpha_{d}=0.80$ ) (i.e., DZP quality). As described in Appendix 2, the addition of polarization functions on the carbon atoms of the azulene skeleton is necessary to obtain a reasonable $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of azulene and its derivatives.

## 3. Results

3.1. Geometries. We preface results with a comment on the 6CNAZ geometrical features. Table 1 presents the optimized parameters for three important conformations (i.e., $\mathrm{S}_{0}$-geometry,

${ }^{a}$ Because of a constraint of $C_{s}$ symmetry, the bond distance of $\mathrm{C}^{2} \mathrm{C}^{1}$, for instance, is identical to that of $\mathrm{C}^{2} \mathrm{C}^{3}$. Similarly, the bond angle of $\mathrm{C}^{2} \mathrm{C}^{1} \mathrm{C}^{10}$ is identical to that of $\mathrm{C}^{2} \mathrm{C}^{3} \mathrm{C}^{9}$. The dihedral angle of $\mathrm{C}^{10} \mathrm{C}^{1} \mathrm{C}^{2} \mathrm{C}^{3}$ is identical to that of $\mathrm{C}^{9} \mathrm{C}^{3} \mathrm{C}^{2} \mathrm{C}^{1}$ with an opposite sign. ${ }^{b}$ Values in the parentheses are optimized parameters of azulene, taken from ref 10 .
$\mathrm{S}_{1}$-geometry, and $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX) of 6 CNAZ , along with those of the parent molecule of azulene. Regarding $\mathrm{S}_{0}$-geometry, the geometrical feature of the azulene skeleton resembles that of azulene. All peripheral CC bond distances are similar to an aromatic CC bond distance. The transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ bond has an almost single CC bond character. Dihedral angles shown in Table 1 indicate that $\mathrm{S}_{0}$-geometry has a planar structure with $C_{2 v}$ symmetry. Therefore, we call $\mathrm{S}_{0}$-geometry an aromatic bond-equivalent structure.

Geometrical features of $S_{1}$-geometry are also similar to those of azulene. The $S_{1}$-geometry has a planar structure with $C_{2 v}$ symmetry as does the $\mathrm{S}_{0}$-geometry (see the relevant dihedral angles in Table 1). However, the skeletal bond distances differ greatly from those at $S_{0}$-geometry. The 6 CNAZ at $\mathrm{S}_{1}$-geometry loses the aromatic bond-equivalent character of $\mathrm{S}_{0}$-geometry. The transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ bond greatly increases the double bond character. Concomitant with the shrinkage of the transannular bond, the peripheral CC bond distances change considerably: $\mathrm{C}^{3} \mathrm{C}^{9}$ and $\mathrm{C}^{9} \mathrm{C}^{4}$ (also $\mathrm{C}^{1} \mathrm{C}^{10}$ and $\mathrm{C}^{10} \mathrm{C}^{8}$ because of the constraint of $C_{s}$ symmetry) that are bonded to the transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ bond lengthen. In fact, $\mathrm{C}^{4} \mathrm{C}^{5}$ shrinks and $\mathrm{C}^{5} \mathrm{C}^{6}$ lengthens.

The skeletal bond distances at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of 6 CNAZ are also similar to that of azulene. The skeletal feature of $S_{1}$-geometry is enhanced at $\mathrm{S}_{1} / \mathrm{S}_{0}-\mathrm{CIX}$ : the $\mathrm{C}^{3} \mathrm{C}^{9}, \mathrm{C}^{4} \mathrm{C}^{9}$, and $\mathrm{C}^{5} \mathrm{C}^{6}$ bonds become longer than those at $S_{1}$-geometry, although the $\mathrm{C}^{4} \mathrm{C}^{5}$ and $\mathrm{C}^{9} \mathrm{C}^{10}$ bonds become shorter. In contrast to the similarities of the skeletal bond distances between 6CNAZ and azulene, the dihedral angles differ greatly from those of azulene. Table 1 shows that the seven-membered ring of 6CNAZ has a planar structure, whereas that of azulene has a nonplanar structure.
3.2. Electronic Structures. This subsection presents discussion of electronic structures in relation to the geometrical features described above. Table 2 shows the electronic structures at $S_{0}$-geometry. The $S_{1}$ state is well described using the highest occupied molecular orbital-lowest unoccupied molecular orbital

TABLE 2: Electronic Structures of 6CNAZ at $\mathbf{S}_{0}$-Geometry

|  |  | dipole moment (Debye) ${ }^{a}$ |  |  |
| :--- | :--- | :---: | :---: | :--- |
|  | energy $(\mathrm{eV})$ |  | $\mu_{z}$ | $\mu_{y}$ |
|  | main CSFs $^{b}$ |  |  |  |
| $\mathrm{~S}_{0}$ | $0.0(0.0)^{c}$ | 3.805 | 0.0 | 0.875 (closed shell) |
| $\mathrm{S}_{1}$ | $2.077(1.713)$ | 5.003 | 0.0 | $0.843\left(1-1^{\prime}\right)$ |

${ }^{a}$ The $z$ - and $y$-directions are defined in Figure 1. ${ }^{b}$ The CSFs of which absolute values of CASSCF coefficients are greater than 0.3 are listed. The five occupied $\pi$-orbitals and the lowest five unoccupied $\pi^{*}$-orbitals in the order of energy are designated, respectively, as $5,4,3,2$, 1 (HOMO), $1^{\prime}(\mathrm{LUMO}), 2^{\prime}, 3^{\prime}, 4^{\prime}$, and $5^{\prime} ; 1-1^{\prime}$ in the parenthesis, for instance, indicates the CSF of single excitation from orbital 1 to $1^{\prime}$. ${ }^{c}$ Values in the parentheses are those by MRMP2.

TABLE 3: Electronic Structures of $\mathbf{6 C N A Z}$ at $\mathbf{S}_{1} / \mathbf{S}_{\mathbf{0}}$-CIX

| energy (eV) ${ }^{\text {b }}$ |  | dipole moment (Debye) ${ }^{a}$ |  | main $\mathrm{CSFs}^{\text {c }}$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  | $\mu_{z}$ | $\mu_{y}$ |  |
| $\mathrm{S}_{0}$ | $1.838(1.366)^{d}$ | 2.532 | -0.005 | $\begin{aligned} & 0.775(\text { closed shell })+ \\ & 0.350(2-1) \end{aligned}$ |
| $\mathrm{S}_{1}$ | 1.844 (1.495) | 4.768 | -0.004 | 0.836 (1-1) |

${ }^{a}$ Because of the nonplanarity at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, the $z$ - and $y$-directions are different from the original space-fixed coordinate in Figure 1. By diagonalizing the tensor of the moment of inertia, we determined the new $z$ - and $y$-directions. The new $z$ - and $y$-components of the moment of inertia correspond, respectively, to the smallest and the largest components. ${ }^{b}$ The energy is relative to that in $\mathrm{S}_{0}$ at $\mathrm{S}_{0}$-geometry. ${ }^{c}$ The CSFs, of which the absolute values of CASSCF coefficients are greater than 0.3 , are listed. The five occupied $\pi$-orbitals and the lowest five unoccupied $\pi^{*}$-orbitals in the order of energy are designated, respectively, as $5,4,3,2,1(\mathrm{HOMO}), 1^{\prime}(\mathrm{LUMO}), 2^{\prime}, 3^{\prime}, 4^{\prime}$, and $5^{\prime} ; 1-1^{\prime}$ in the parenthesis, for instance, indicates the CSF of single excitation from orbital 1 to $1^{\prime} .{ }^{d}$ Values in parentheses are those by MRMP2.

HOMO

LUMO

Figure 2. HOMO and LUMO at $S_{0}$-geometry.

Figure 3. 6CNAZ divided into fragments.
(HOMO-LUMO) single excitation. Figure 2 shows that the character of molecular orbitals (MOs) in the transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ part changes from an antibonding (in HOMO) orbital into a bonding (in LUMO) orbital, which engenders shrinkage of the transannular bond in $\mathrm{S}_{1}$. The changes of the peripheral CC bonds in $S_{1}$ can also be related to changes of the MO nature in relevant parts.

Table 3 lists the electronic structure at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX using (10,10)CASSCF. The energy difference $(0.006 \mathrm{eV})$ is sufficiently small to be a CIX, which implies that $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX by $(8,8)$ CASSCF described above is similar to $\mathrm{S}_{1} / \mathrm{S}_{0}$ - CIX by $(10,10)$ CASSCF which is impractical because of an extremely large computational load. The main configuration state functions (CSFs) indicate that $S_{0}$ and $S_{1}$ are well described, respectively,
by the closed-shell CSF and the HOMO-LUMO single excitation, which is similar to the case for electronic structures at $S_{0}$-geometry (see Table 2) and those of $\mathrm{S}_{1}$-geometry.
3.3. Dipole Moments. The dipole moments and charge populations are useful to deepen understanding of the 6CNAZ photochemical process. Table 4 presents dipole moments and the charge populations at important conformations along with those of azulene. Figure 3 shows the definition of each fragment for the charge population. The change of the dipole moments of 6CNAZ (1.198 D) at $\mathrm{S}_{0}$-geometry resembles that of azulene $(1.004 \mathrm{D})$ because some charge in fragment A transfers to the remaining parts (especially fragment $C$ ) through electronic excitation into $S_{1}$ in cases of 6 CNAZ and azulene.

The dipole moment for $S_{1}$-geometry resembles that for $S_{0^{-}}$ geometry. However, the charge population in each fragment changes; some charges in A and C move into the transannular part B, which is related to the geometrical change by which the transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ bond increases its double bond character during the process of $\mathrm{S}_{0}$-geometry $\rightarrow \mathrm{S}_{1}$-geometry in $\mathrm{S}_{1}$. The charge transfer into B continues, reflecting the increasing double-bond character of the transannular $\mathrm{C}^{9} \mathrm{C}^{10}$ bond during the process of $\mathrm{S}_{1}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. A similar discussion can also be made for the case of the $S_{1}$-geometry $\rightarrow S_{1} / S_{0}$-CIX process of azulene, as far as the charge in B is concerned (Table 4). Nevertheless, $S_{1} / S_{0}$-CIX of 6CNAZ differs greatly from that of azulene; the former takes a planar structure in the sevenmembered ring, whereas the latter is nonplanar. The charge population of fragment C in $\mathrm{S}_{1}$ can explain this geometrical difference. As Table 4 shows, the charge population in C is much less negative than that of azulene. Therefore, the structure around the $\mathrm{C}^{6}$ atom of 6 CNAZ resembles a planar carbocation, whereas that of azulene resembles a nonplanar carbanion.

At $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, the dipole moment in $\mathrm{S}_{1}$ (long-axis component; $4.768 \mathrm{D})$ changes suddenly into that in $\mathrm{S}_{0}(2.532 \mathrm{D})$, which differs greatly from that for $S_{0}$-geometry. The decrease of the dipole moment ( 2.236 D ) is comparable to that of azulene (long axis component; 1.733 D ). Therefore, the large difference of the $\mathrm{S}_{0}$ dipole moment between $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX and $\mathrm{S}_{0}$-geometry is ascribed to the fact that the nonaromatic azulene skeleton at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX is very different from the aromatic one for $\mathrm{S}_{0}-$ geometry.

Summarizing the role of the cyano group in the $S_{1-} S_{0}$ IC of 6CNAZ, Table 4 shows that the charge population in the cyano group is almost constant, irrespective of the conformation or electronic state. Furthermore, the CN and $\mathrm{C}^{6} \mathrm{C}$ bond distances remain almost unchanged, as shown in Table 1. Therefore, the electron-withdrawing capability of the cyano group is almost constant in all $S_{1}-S_{0}$ IC processes, which is related to the fact that many similarities are apparent in the computational findings between 6CNAZ and the parent azulene, as described above. The electron-withdrawing capability of the cyano group produces an interesting difference at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX: the planar seven-membered ring for 6 CNAZ and the nonplanar one for azulene.
3.4. Prediction of $\mathbf{S}_{\mathbf{1}}-\mathbf{S}_{\mathbf{0}}$ IC Process. To predict the $\mathrm{S}_{1}-\mathrm{S}_{0}$ IC of 6CNAZ, we briefly review the previously reported picture of azulene. ${ }^{10}$ Figure 4 a shows that the $\mathrm{S}_{1}-\mathrm{S}_{0}$ IC process of azulene schematically. Upon excitation into $S_{1}$ at aromatic bondequivalent $S_{0}$-geometry, azulene is skeletally relaxed into a planar but nonaromatic $\mathrm{S}_{1}$-geometry. After passing through the region around $S_{1}$-geometry, a nonplanarity in the sevenmembered ring becomes important so that azulene reaches $\mathrm{S}_{1} /$ $\mathrm{S}_{0}$-CIX. The energetic instability in the process of $\mathrm{S}_{1}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX ( 0.426 eV in Table 5) is comparable to the

energetic stability between $\mathrm{S}_{0}$-geometry and $\mathrm{S}_{1}$-geometry ( 0.396 eV ). These computational findings can be related to the experimental findings EXP1 to EXP3 described in the Introduction. During the stay in $S_{1}$, azulene is subjected to a large geometrical change from $S_{0}$-geometry into $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. The period of the stay in $S_{1}$ corresponds to the experimental decay time ( $1-2 \mathrm{ps}$ ) (4-9). The excess energy of $1000-1300 \mathrm{~cm}^{-1}$ above the $S_{1}$ origin drastically decreases the lifetime (ca. 0.4 ps ) or broadening of the rotational line width. ${ }^{4,8}$ In this region, several totally symmetric in-plane (i.e., a $a_{1}$-type under $C_{2 v}$ ) vibrations exist. One vibrationally excited-state in $S_{1}$ can facilitate azulene's change from $S_{0}$-geometry into $S_{1}$-geometry. Therefore, azulene with excess energy of $1000-1300 \mathrm{~cm}^{-1}$ in $S_{1}$ can pass over $S_{1}$-geometry and reach $S_{1} / S_{0}$-CIX more effectively. Two computational findings related to the process of $\mathrm{S}_{1}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, i.e., the nonplanarity of the sevenmembered ring and the energetic instability, can be related to

Bond-equalized

Bond-alternant

Figure A1. Aromatic bond-equalized structure and nonaromatic bondalternant structure of 6CNAZ.
the experimental observation of strong oscillations because of the out-of-plane motions that occur before the decay. ${ }^{4}$ To reach $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX from $\mathrm{S}_{0}$-geometry in $\mathrm{S}_{1}$, the out-of-plane motion in the seven-membered ring is necessary, but it does not play an important role until electronically excited azulene passes over the most stable geometry in $S_{1}$ (i.e., $S_{1}$-geometry). In other words, the out-of-plane motion in the seven-membered ring is promoted on the impulsive $S_{1}$ potential energy surface between $\mathrm{S}_{1}$-geometry and $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. Therefore, any out-of-plane vibration is inactive in the $S_{0}-S_{1}$ electronic transition; nevertheless, the strong oscillation of the out-of-plane mode occurs before the decay.

Now we predict the $S_{1}-S_{0}$ IC of 6 CNAZ . As presented in Table 5, the energetic stability in the process of $\mathrm{S}_{0}$-geometry $\rightarrow \mathrm{S}_{1}$-geometry in $\mathrm{S}_{1}(0.528 \mathrm{eV})$ is similar to that of azulene, whereas the energetic instability of $\mathrm{S}_{1}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX $(0.295 \mathrm{eV})$ is much smaller. As for azulene, 6 CNAZ is subject to a similar large skeletal change in the process of $\mathrm{S}_{0}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. Therefore, we predict that the lifetime in $\mathrm{S}_{1}$ of 6 CNAZ is shorter than that of azulene in equivalent experimental conditions. Furthermore, using vibrational analysis at
$\mathrm{S}_{0}$-geometry, we found that several totally symmetric in-plane vibrations exist in the region of $1000-1300 \mathrm{~cm}^{-1}$. Therefore, the excess energy of $1000-1300 \mathrm{~cm}^{-1}$, which serves 6 CNAZ to deform from aromatic $\mathrm{S}_{0}$-geometry into nonaromatic $\mathrm{S}_{1}$ geometry, is likely to shortening the decay time drastically, as found in case of azulene. Finally, we predict oscillatory signals because the out-of-plane vibrations are slight or nonexistent in the decay of 6CNAZ, which can be explained as (i) a planar structure at $S_{1} / S_{0}$-CIX or (ii) slight energetic instability in the process of $\mathrm{S}_{1}$-geometry $\rightarrow \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX.

Before terminating the prediction of the $S_{1-} S_{0}$ IC of 6CNAZ, we examine the reliability of the present discussion based on the CASSCF results. Table 5 shows that the MRMP2 energetic corrections are not so different from each other, irrespective of conformations and electronic states. For that reason, the above discussion based on the CASSCF results will change greatly by use of a more sophisticated MRMP2 method. It is expected that the MRMP2 discussion on the $S_{1}-S_{0}$ IC of 6CNAZ would be changed because the global potential energy surfaces are commonly shifted-down by ca. 0.3 eV . In Figure 4b, we show a schematic representation of the $S_{1-} S_{0}$ IC of 6CNAZ, in which the MRMP2 effect is considered.

## 4. Concluding Remarks

In this study, we predicted the $S_{1}-S_{0}$ IC of 6 CNAZ in comparison with that of azulene. Results show that many similarities of the geometries and the electronic states exist between 6 CNAZ and azulene. At the stable geometry in $\mathrm{S}_{0}$, all peripheral bonds are similar to a CC bond distance of aromatic benzene; furthermore, the transannular bond resembles a CC single bond. Upon electronic excitation into $S_{1}$, however, the aromaticity is lost, and the transannular bond greatly increases its double bond character so that 6CNAZ is skeletally relaxed with a planar structure in $\mathrm{S}_{1}$. In addition, $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of 6 CNAZ contrasts to that of azulene. The former almost retains its planar structure in the seven-membered ring and does not become energetically unstable to a great degree relative to the stable geometry in $\mathrm{S}_{1}$ (i.e., $\mathrm{S}_{1}$-geometry). The latter takes a nonplanar conformation and becomes unstable relative to $S_{1}$-geometry. The electron-withdrawing cyano group plays an important role in creating a planar structure at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. On the basis of these computational findings, we were able to predict the experimental findings for $S_{1}-S_{0}$ IC of 6CNAZ:
i) The excess energy of $1000-1300 \mathrm{~cm}^{-1}$ above the $S_{1}$ origin drastically decreases the lifetime in $S_{1}$, as observed also in case of azulene.
ii) The lifetime in $S_{1}$ is likely to be shorter than that of azulene because the energetic location of $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX relative to the $\mathrm{S}_{1}$ state is lower than that of azulene.
iii) In contrast to the case of azulene, little or no oscillatory signal attributable to the low-frequency out-of-plane motions is expected.

To verify our predictions of the $S_{1-} S_{0}$ IC of 6 CNAZ and to justify our interpretation on that of azulene, we hope to use an experimental approach on the photochemistry of 6CNAZ.

## Appendix 1

As clarified previously, ${ }^{10,14}$ the stable geometry of azulene in $\mathrm{S}_{0}$ is strongly dependent on its computational method. We investigated whether the stable geometry of 6 CNAZ in $\mathrm{S}_{0}\left(\mathrm{~S}_{0^{-}}\right.$ geometry) is dependent on the computational method. Two possible conformations of $\mathrm{S}_{0}$-geometry (Figure A1) exist: an aromatic bond-equalized conformation in which all peripheral CC bonds are similar to an aromatic CC bond; and a bondalternant conformation, by which a peripheral CC skeleton alternates the $\mathrm{C}=\mathrm{C}$ double bond with the $\mathrm{C}-\mathrm{C}$ single bond. In Table A1, we listed the optimized skeletal bonds with our present basis set described in section 2. Although the stable geometry in $\mathrm{S}_{0}$ has a planar structure in any computational method, only the second-order Möller-Plesset perturbation (MP2) method gives a bond-equivalent structure (i.e., $C_{2 v}$ geometry); the other methods give a bond-alternant structure (i.e., $C_{s}$ geometry). We then performed a CASSCF optimization under constraint of $C_{2 v}$ symmetry. As presented in Table A1, the optimized geometry under $C_{2 v}$ constraint yields a similar result to that using MP2 method. At the $C_{s}$ and $C_{2 v}$ CASSCF geometries, we made energetic Multireference MP2 (MRMP2) corrections. The $C_{2 v}$ geometry (i.e., aromatic bond-equalized structure) is more stable by 0.554 eV than the $C_{s}$ geometry (bond-alternant structure) with MRMP2 correction, although it is unstable by 0.870 eV without MRMP2 correction (i.e., only CASSCF). On the basis of these computational findings, we must impose a $C_{2 v}$ symmetry constraint to obtain a reasonable bond-equalized structure in $\mathrm{S}_{0}$ by the present $(10,10)$ CASSCF method. However, 6 CNAZ can take a nonplanar structure, especially at $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX, as indicated in the text. We loosened the geometrical constraint from $C_{2 v}$ into $C_{s}$ symmetry, in which the $y z$-plane in Figure 1 is a symmetry plane.

We also examined whether geometries in $\mathrm{S}_{1}$ are frustrated under the constraint of $C_{s}$ symmetry of the $y z$-plane. We performed vibrational analyses at several conformations with $C_{s}$ symmetry ranging from $\mathrm{S}_{0}$-geometry to $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. Results showed no imaginary frequency in $S_{1}$ for any conformation, although only one imaginary frequency in $\mathrm{S}_{0}$ exists for each conformation (e.g., $416 i \mathrm{~cm}^{-1}$ at $\mathrm{S}_{0}$-geometry) leading to a bondalternate structure. For that reason, the $S_{1}$ state is destabilized by a vibration leading to a bond-alternant structure, irrespective of conformations, whereas the $\mathrm{S}_{0}$ state is stabilized incorrectly at the level of CASSCF calculation. This is identical to the case of azulene. ${ }^{10}$ Therefore, we can say that the $C_{s}$ symmetry constraint of $y z$-plane serves to give a more reasonable structure in $S_{0}$ than in either $S_{1}$ or $S_{0}$. Considering these computational findings, it seems natural that $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX has $C_{s}$ symmetry of the $y z$-plane. Actually, we performed an $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX optimization

without any symmetry constraint to obtain the same $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. For those reasons, our present calculation, in which the $C_{s}$ symmetry constraint is imposed, is proper to obtain reasonable structures and to reduce the computational load.

## Appendix 2

As clarified in our previous paper, ${ }^{10} \mathrm{~S}_{1} / \mathrm{S}_{0}$-CIX has a nonplanar structure in the seven-membered ring, whereas $\mathrm{S}_{1} /$ $\mathrm{S}_{0}$-CIX by Bearpark et al. has a substantially planar structure. ${ }^{3}$ To examine their differences, we performed an additional $\mathrm{S}_{1} /$ $\mathrm{S}_{0}$-CIX optimization of the parent molecule of azulene using $(8,8)$ CASSCF with a double- $\zeta$ (DZ) basis set; the active space is identical, but the polarization functions on the carbon atoms of the azulene skeleton are removed. Table A2 portrays $S_{1} / S_{0^{-}}$ CIX using three computation types. Apparently, $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX without polarization functions (i.e., DZ quality) tends to take a planar structure. In other words, the polarization functions on the carbon atoms of the azulene skeleton (i.e., DZP) are important to ensure the flexibility of $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX. In the present computation of $6 \mathrm{CNAZ}, \mathrm{S}_{1} / \mathrm{S}_{0}$-CIX takes a planar structure even by addition of the polarization functions on the azulene skeleton,
which implies that a planar $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of 6 CNAZ and a nonplanar $\mathrm{S}_{1} / \mathrm{S}_{0}$-CIX of azulene are realistic conformations.
