

been proposed which are consistent with the observed twinning behavior and cell symmetry. The same ordered structures are suggested for HUP from our observations of the twinning behavior.

*Studies of Layered Uranium (VI) Compounds. IV. Proton Conductivity in Single-Crystal Hydrogen Uranyl Phosphate Tetrahydrate (HUP) and in Polycrystalline Hydrogen Uranyl Arsenate Tetrahydrate (HUAs).* ARTHUR T. HOWE AND MARK G. SHILTON. Department of Inorganic and Structural Chemistry, University of Leeds, Leeds LS2 9JT, England.

Single-crystal measurements on hydrogen uranyl phosphate tetrahydrate,  $\text{H}_2\text{UO}_2\text{PO}_4 \cdot 4\text{H}_2\text{O}$  (HUP), have confirmed that the high proton conductivity is a bulk characteristic. The conductivity values were in substantial agreement with those previously reported for polycrystalline disks. A conductivity of  $0.6 \text{ ohm}^{-1} \text{ m}^{-1}$  at  $290^\circ\text{K}$  and an activation energy of  $30 \pm 1 \text{ kJ mole}^{-1}$  were measured parallel to the structural layers of the crystal. The conductivity was at least 100 times lower when measured in the perpendicular direction. A reasonable attempt frequency  $\omega_0$  of approximately  $10^{15} \text{ Hz}$  could be derived from the parallel conductivity on the assumption that the charge carrier concentration was equal to that of the  $\text{H}_3\text{O}^+$  ions. This implies a low proton mobility, of the order of  $10^{-9} \text{ m}^2 \text{ V}^{-1} \text{ sec}^{-1}$  at  $290^\circ\text{K}$ , in support of previous estimates. We have also shown that polycrystalline hydrogen uranyl tetrahydrate,  $\text{H}_2\text{UO}_2\text{AsO}_4 \cdot 4\text{H}_2\text{O}$  (HUAs), has a high conductivity of  $0.6 \text{ ohm}^{-1} \text{ m}^{-1}$  at  $310^\circ\text{K}$ , with an activation energy of  $31 \pm 2 \text{ kJ mole}^{-1}$ . Below the respective dielectric ordering transition temperatures of HUP and HUAs of  $274$  and  $301^\circ\text{K}$ , the lower conductivity values show a marked frequency dependence, which may be due to dispersion effects caused by water reorientations.

*Topotaxial Decomposition of Calcite-Type  $\text{KNO}_3$  Crystals.* S. W. KENNEDY AND W. M. KRIVEN. Department of Physical and Inorganic Chemistry, University of Adelaide, Adelaide, S.A. 5001, Australia.

The calcite-like form of potassium nitrate,  $\text{KNO}_3$ , decomposed under the transmission electron microscope to form  $\text{KNO}_2$  which subsequently decomposed giving the high-temperature  $\beta$  form of  $\text{K}_2\text{O}$ . Two closely related orientation relations were observed for  $\text{KNO}_2$ . Referred to the four molecule cell of  $\text{KNO}_3$ , they were  $[111]_{\text{KNO}_3} \parallel [111]_{\text{KNO}_2}$ ,  $(0\bar{1}1)_{\text{KNO}_3} \parallel (0\bar{1}1)_{\text{KNO}_2}$ ; and  $[100]_{\text{KNO}_3} \parallel [100]_{\text{KNO}_2}$ ,  $(001)_{\text{KNO}_3} \parallel (001)_{\text{KNO}_2}$ . These and a different published orientation relation for the decomposition of cadmium carbonate conform, respectively, to orientations resulting from a corresponding structural phase transformation in rubidium nitrate.  $\beta\text{-K}_2\text{O}$  formed with its cube axes parallel to those of  $\text{KNO}_2$ . Both nitrate and carbonate reactions can be regarded as topotaxial. Application of the crystallographic approach to orientations and accommodation of misregistry is discussed.

*Structure Cristalline de la Phase  $\beta\text{-KEr}_2\text{F}_7$  Composés Isotypes.* S. ALEONARD, Y. LE FUR, M. F. GORIUS ET M. TH. ROUX. Laboratoire de Cristallographie, CNRS 166X-38042 Grenoble Cedex, France.

Potassium erbium fluoride  $\beta\text{-KEr}_2\text{F}_7$  crystallizes in the orthorhombic system, space group  $Pna2_1$ , with the unit-cell dimensions  $a = 11.820 \text{ \AA}$ ,  $b = 13.333 \text{ \AA}$ ,  $c = 7.816 \text{ \AA}$  ( $Z = 8$ ). The crystal structure has been solved from single-crystal diffractometer measurements ( $\text{AgK}\alpha$ ) by Patterson and Fourier synthesis and refined by a least-squares method. The final  $R$  value is 0.042 for 2374 independent observed reflections ( $R_w = 0.051$ ). The four species of erbium atoms are surrounded by eight fluorine atoms. These fluorine atoms form, respectively, three quadratic antiprisms and one dodecahedron, derived from a distorted cube. Two antiprisms and the dodecahedron share two of their faces to form  $(\text{Er}_3\text{F}_{17})^{8-}$  groups. These groups are bidimensionally linked and the planes they form are joined together by the third antiprism. A three-dimensional network is then produced, in the tunnels of which potassium atoms are located. Lattice parameters of compounds which are isotypes to the new structure type of  $\beta\text{-KEr}_2\text{F}_7$  are given.

*Thermodynamische Untersuchungen am System  $\text{CoO}/\text{MgO}$ .* K. TORKER UND W. INSELSBACHER. Institut für Physikalische und Theoretische Chemie, Technische Universität Graz, A-8010, Austria.

A series of solid solutions,  $\text{Co}_x\text{Mg}_{1-x}\text{O}$ , was studied thermodynamically in the range  $1100\text{--}1300 \text{ K}$  by means of solid state galvanic cells using oxygen-ion conductors. The activities of  $\text{CoO}$  in the solid solutions show positive deviations from Raoult's law. The solid solutions are interpreted to be regular within the
