Received March 12, 1991; in revised form August 9, 1991

$\beta\text{-PrZr}_3\text{F}_{15}$ , a new low temperature ( $<800^\circ\text{C}$ ) variety in the  $M\text{Zr}_3\text{F}_{15}$  series, crystallizes in the rhombohedral, noncentrosymmetrical  $R3m$  space group, with the hexagonal parameters  $a = 12.316(8)$ ,  $c = 6.115(4)$  Å ( $Z = 3$ ). The crystal structure was solved on the basis of single crystal data ( $R = 0.033$ ). It is derived from the  $\text{ReO}_3$  type by a structural mechanism, thoroughly described, involving full cationic ordering and ordered insertion of excess anions, transforming the  $MX_6$  octahedra respectively into corner-shared  $[\text{ZrF}_7]^{3-}$  pentagonal bipyramids and  $[\text{PrF}_9]^{6-}$  tricapped trigonal prisms.  $\beta\text{-PrZr}_3\text{F}_{15}$  can thus be considered as a new member of the structural family of anion-excess  $\text{ReO}_3$ -related phases such as  $\text{SmZrF}_7$ ,  $\text{Zr}(\text{O},\text{F})_{3+x}$ ,  $\beta\text{-BaZr}_2\text{F}_{10}$ ,  $\text{Bi}(\text{Y})\text{Zr}_3\text{F}_{15}$ , and cubic  $(\text{Zr},\text{M})\text{F}_{3+x}$  phases. © 1992 Academic Press, Inc.

### Introduction

Among the various  $M\text{F}_3\text{-M}'\text{F}_4$  systems, namely  $\text{LnF}_3\text{-ZrF}_4$  (1–3),  $\text{LnF}_3\text{-HfF}_4$  (3),  $\text{LnF}_3\text{-TbF}_4$  (4),  $M\text{F}_3\text{-ZrF}_4$  ( $M = \text{Ti}, \text{In}$  (5),  $\text{U}^{\text{III}}$  (6),  $\text{Bi}$  (7)),  $\text{UF}_3\text{-UF}_4$  (8) and  $\text{InF}_3\text{-UF}_4$  (9), some have been thoroughly investigated. However, only few structure types are described: monoclinic  $\text{SmZrF}_7$  (10), rhombohedral  $\text{BiZr}_3\text{F}_{15}$  (7) and  $\text{YZr}_3\text{F}_{15}$  (11) compounds, and cubic  $\text{ReO}_3$ -type and trigonal tysonite-type solid solutions.

The present article deals with the description of a new structure type:  $\beta\text{-PrZr}_3\text{F}_{15}$ , a low temperature  $M\text{Zr}_3\text{F}_{15}$  polymorph, previously unknown and isolated also for  $M = \text{Nd}$ .

### Experimental

In the  $\text{PrF}_3\text{-ZrF}_4$  system, at temperatures higher than  $800^\circ\text{C}$ , a nonstoichiometric phase of structure related to that of  $\text{BiZr}_3\text{F}_{15}$  and  $\text{YZr}_3\text{F}_{15}$  has been prepared and characterized (11) as the  $\alpha\text{-PrZr}_3\text{F}_{15}$  phase. At  $800^\circ\text{C}$ , a new stoichiometric phase, called  $\beta\text{-PrZr}_3\text{F}_{15}$ , is obtained pure by heating a mixture of praseodymium and zirconium fluorides in  $\frac{1}{3}$  proportion for 2 days in a Pt sealed tube.

Single crystals of good quality were grown in a two-phase mixture of composition  $\text{PrF}_3\text{-5ZrF}_4$  heated at  $800^\circ\text{C}$  for 2 days in a Pt sealed tube and then water-quenched. The crystallographic characteristics of  $\beta\text{-PrZr}_3\text{F}_{15}$  and of isomorphous  $\beta\text{-NdZr}_3\text{F}_{15}$  are reported in Table I.

A single crystal of light green color and

regular shape was isolated for structure investigation. It was assimilated to a sphere of 0.17 mm diameter and its X-ray diffraction intensities were recorded on a NONIUS-C.A.D. 4 automatic diffractometer under the conditions reported in Table II. Due to the low  $\mu R$  coefficient ( $\approx 0.6$ ), no absorption correction was performed.

### Structure Determination

Structure refinement was carried out with the program SHELX-76 (12), utilizing the scattering factors and the anomalous dispersion factors taken from the International Tables for X-Ray Crystallography (13).

By analysis of the Patterson function, the

TABLE II  
DATA COLLECTION PARAMETERS

Symmetry: rhombohedral (space group: $R\bar{3}m$ ; no. 160)
Crystal radius: 0.08 mm
$\mu R = 0.6$

Scan: $\omega$ -2 $\theta$
Scan width: (1. + 0.35tg $\theta$ )°
Aperture: (3. + 1.tg $\theta$ ) mm.
Recording range:
0 $\leq h \leq +22$
0 $\leq k \leq +22$
-11 $\leq l \leq +11$
Number of measured reflections: 564
Number of weak reflections: 72
Number of observed reflections with $I/\sigma(I) > 0.5$ : 445 <sup>a</sup>
Number of refined variables: 36
No weighting scheme.
No absorption correction.
$R = 0.033$ ; $R_w = 0.033$

<sup>a</sup> This low value of  $I/\sigma(I)$  was selected because of unusually high  $\sigma(I)$  coefficients resulting from a slight instability of the X-ray generator during data collection, but without high loss of accuracy, as attested by structure refinement.

cationic positions were determined in the noncentrosymmetrical  $R\bar{3}m$  (no. 160) space group (hexagonal multiple cell), with an ordered distribution of Pr<sup>3+</sup> ( $3a$ : 0, 0,  $z$ ) and Zr<sup>4+</sup> ( $9b$ :  $x$ ,  $-x$ ,  $z$ ) atoms. After several cycles of refinement, the  $R$ -factor converged to 11.2%. Then, a Fourier-difference synthesis revealed four anionic sites. Refinement of all atomic positions and isotropic thermal factors led to  $R = 4.7\%$  and after introduction of anisotropic temperature factors for all atoms, the  $R$ -factor converged to  $R = 3.3\%$  with reasonable values for all parameters. No improvement resulted either from the introduction of a weighting scheme or of a secondary extinction correction.

The structural parameters are reported in Table III and the main interatomic distances in Table IV.

### Structure Description

The projection of the structure of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> onto the hexagonal  $xoy$  plane is represented in Fig. 1.

#### (a) Anionic Polyhedra

Two kinds of anionic polyhedra are shown in Fig. 2.

**Pentagonal bipyramid** [ZrF<sub>7</sub>]<sup>3-</sup>. Its pentagonal basis is made up of four F<sub>4</sub> ( $d_{Zr-F} = 2.123(6)$  and  $2.167(6)$  Å) and one F<sub>3</sub> ( $d_{Zr-F} = 2.023(9)$  Å) anions. Both F<sub>2</sub> and F<sub>1</sub> apical anions are closer to the Zr cation (respectively 1.957(9) and 1.967(8) Å).

**Tricapped trigonal prism** [PrF<sub>9</sub>]<sup>6-</sup>. Three F<sub>2</sub> and three F<sub>3</sub> anions respectively form the two opposite triangular faces of the trigonal prism, with the shortest Pr-F bonds Pr-F<sub>2</sub> = 2.360(9) Å and Pr-F<sub>3</sub> = 2.331(9) Å. Three F<sub>1</sub> anions cap the lateral faces with longer Pr-F distances (2.438(9) Å).

#### (b) Structure Organization

Each [ZrF<sub>7</sub>]<sup>3-</sup> pentagonal bipyramid (P.B.) is corner-shared to four identical ones

F <sub>2</sub> 9b	4074(5)	5926	4585(15)	208(33)	208	155(40)	113(37)	-56(19)	56	1.5(3)
F <sub>3</sub> 9b	4121(7)	5879	9076(24)	256(37)	256	472(60)	81(43)	-186(28)	186	2.6(4)
F <sub>4</sub> 18c	6283(6)	5860(6)	4422(9)	107(25)	160(27)	106(18)	69(22)	35(18)	9(18)	1.0(2)

<sup>a</sup> Constrained parameter.

and three [PrF<sub>9</sub>]<sup>6-</sup> tricapped trigonal prisms (T.T.P.). Likewise, each [PrF<sub>9</sub>]<sup>6-</sup> polyhedron is corner-shared to nine P.B. Therefore, Pr and Zr cations only connected through F corners are rather distant from one another (Zr-Zr = 4.185 Å, Zr-Pr = 4.178, 4.353, and 4.309 Å). Two Pr and six Zr cations constitute a rather distorted P cubic subunit, Pr atoms occupying two opposite corners, along a parallel to the [001] axis of the hexagonal multiple cell (e.g., in Fig. 1: Pr (0.33, 0.67, 0.17 and 0.33, 0.67,

1.17), associated with the six nearest Zr cations with  $z = 0.67$  and  $z = 1.00$ ).

A close structural relationship between  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> and the ReO<sub>3</sub> type is clearly evident in Fig. 3 which shows a perspective drawing of (a) ReO<sub>3</sub> structure; (b) the distorted P cubic subunit of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> considering only the eight cations of the subcell and the F anions linking these cations; (c) the same subunit with all the anions which build the P.B. and the T.T.P. These [PrF<sub>9</sub>]<sup>6-</sup> and [ZrF<sub>7</sub>]<sup>3-</sup> polyhedra, sharing F<sub>1</sub>, F<sub>2</sub>, or

			F <sub>4</sub> '-F <sub>2</sub> = 3.019(15)
			F <sub>3</sub> -F <sub>1</sub> = 3.013(17)

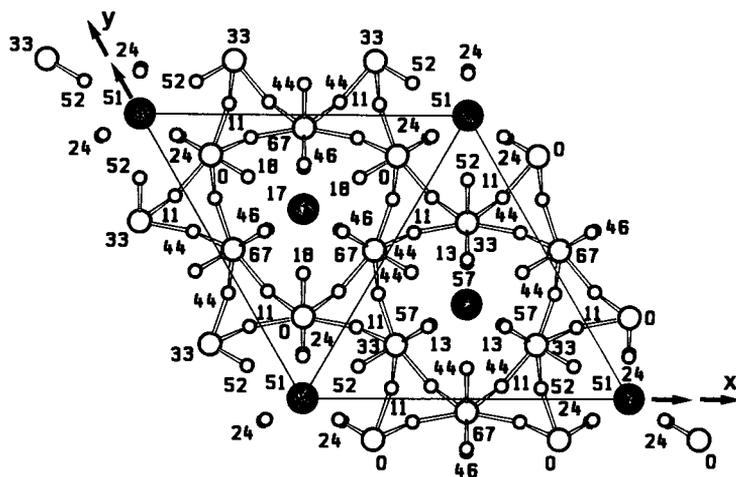

FIG. 1. (001) projection of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> (hexagonal cell). Numbers indicate  $z$  coordinate of atoms ( $\times 100$ ). For drawing clearness, only  $0 \leq z \leq 0.67$  coordinates and only Zr–F chemical bonds are represented. Pr, dark large spheres; Zr, light large spheres; F, small spheres.

F<sub>4</sub> corners, constitute a “PrZr<sub>3</sub>F<sub>12</sub>” unit with a ReO<sub>3</sub>-like structure. The F<sub>3</sub> anions are excess ones, directly connecting one Pr and one Zr cation situated in the opposite corners of a side of the ReO<sub>3</sub>-like subcell. Therefore, this almost square face is transformed into two triangular ones via shortening of Pr–Zr distance from  $\approx 4.2\sqrt{2}$  Å to 4.353 Å. Each Pr<sup>3+</sup> polyhedron (Fig. 3b)

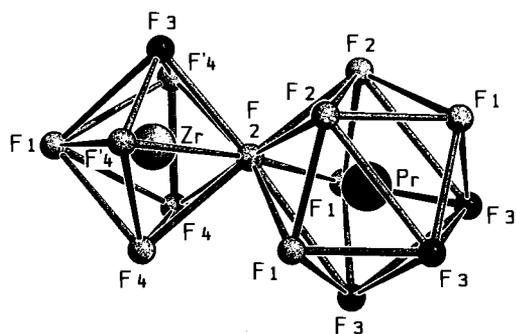

FIG. 2. Perspective drawing of corner-shared  $[\text{ZrF}_7]^{3-}$  pentagonal bipyramid and  $[\text{PrF}_9]^{6-}$  tricapped trigonal prism. Darker small spheres (F<sub>3</sub> anions) refer to the structural mechanism of Figs. 3 and 6.

shares three F<sub>3</sub> anions with three Zr<sup>4+</sup> polyhedra of the three adjacent square faces of a same subcell, about a three-fold axis. This bridging results in a shift of Pr cations along the  $O_z$  hexagonal axis and thus is the main cause of the distortion of the P cubic subcell.

Like the ReO<sub>3</sub> one, the three-dimensional structure of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> results from the stacking of identical layers of corner-shared anionic polyhedra. Figure 4 represents such a basic layer: the bridging of Pr and Zr cations, transforming one square face into two triangular ones, is clearly evident. The cationic plane net (Fig. 5c) in this basic layer (called  $[3.4^3][3^2.4.3]^2$  with Schläfli notation) is very close to a  $3^2.4.3.4$  one (Fig. 5b), an important semiregular net in the classification of O’Keeffe and Hyde (14), present in many alloy structures (Pb<sub>3</sub>Ge, CuAl<sub>2</sub>, Ir<sub>3</sub>Si, . . .) and transitional between regular 3<sup>6</sup> (triangular) and 4<sup>4</sup> (square) nets. The transformation of a 4<sup>4</sup> square net, like the ReO<sub>3</sub> cationic one, into a 3<sup>2</sup>.4.3.4. net can be described as resulting either from a  $\pi/12$  rotation of square groups of atoms about a four-fold axis or from the direct conversion of

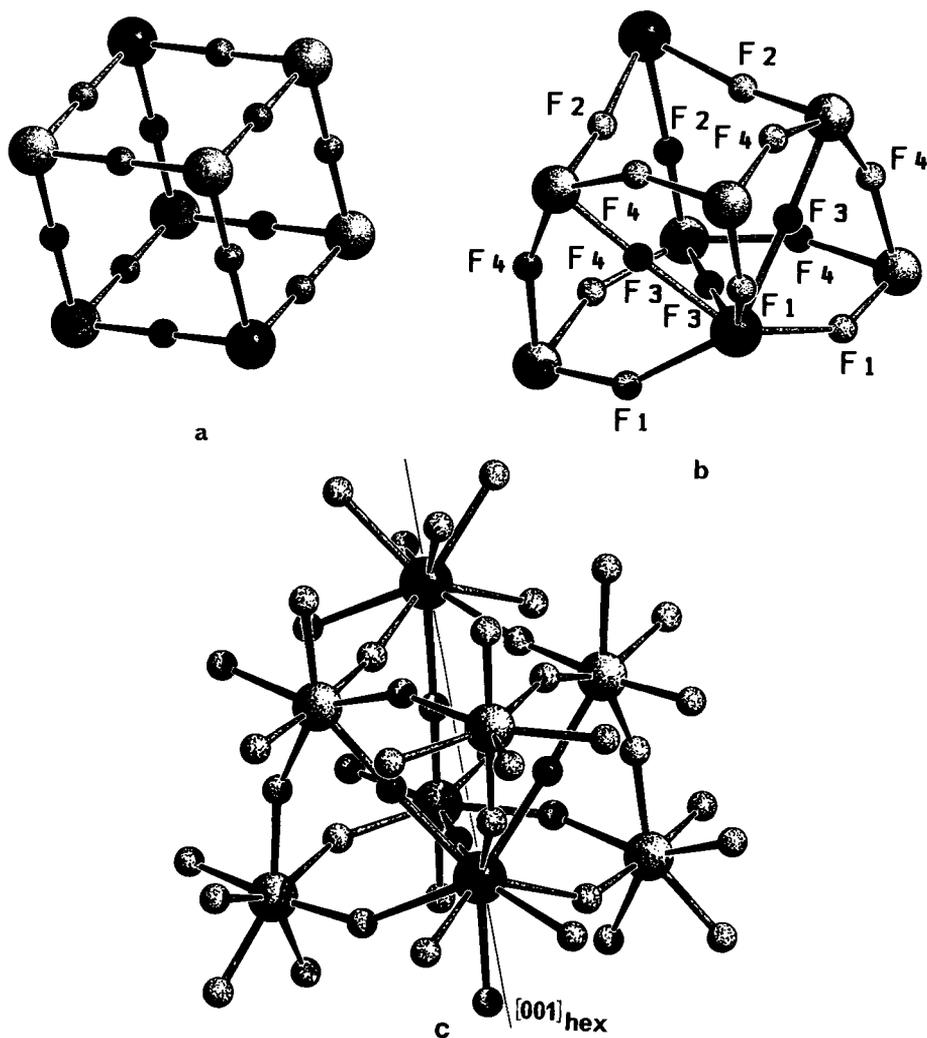

FIG. 3. Comparison of the structures of: (a),  $\text{ReO}_3$ ; (b),  $\beta\text{-PrZr}_3\text{F}_{15}$  with a perspective view of a  $\text{ReO}_3$ -like network, including only anions directly connecting Pr and Zr cations; (c),  $\beta\text{-PrZr}_3\text{F}_{15}$  with the same perspective view showing the  $\text{ReO}_3$ -like association of two  $[\text{PrF}_9]^{6-}$  and six  $[\text{ZrF}_7]^{3-}$  polyhedra enclosing an empty cavity. Pr, darker large spheres; Zr, lighter large spheres; F, small spheres;  $\text{F}_3$ , darker small spheres ("excess" anions).

half square faces into  $60^\circ$  rhombuses (as shown by arrows in Fig. 5a). In the  $\beta\text{-PrZr}_3\text{F}_{15}$  plane net, such a conversion is obviously related to  $\text{F}_3$  bridging between Pr and Zr cations. However, this bridging affects only a quarter of square faces in the  $[3.4^3][3^2.4^3]^2$  plane net and not a half as in a  $3^2.4.3.4$  one. This distribution of triangular and square faces cannot give a regular plane

net. Therefore, small shifts of Pr and Zr cations occur, distorting the square faces and twisting the plane net in such a way that its projection appears like a true  $3^2.4.3.4$  one (Figs. 5b and 5c).

Considering the structural relationship between  $\beta\text{-PrZr}_3\text{F}_{15}$  and  $\text{ReO}_3$ ,  $[\text{ZrF}_7]^{3-}$  and  $[\text{PrF}_9]^{6-}$  polyhedra directly derive from  $\text{MF}_6$  octahedra by adding the  $\text{F}_3$  excess anions

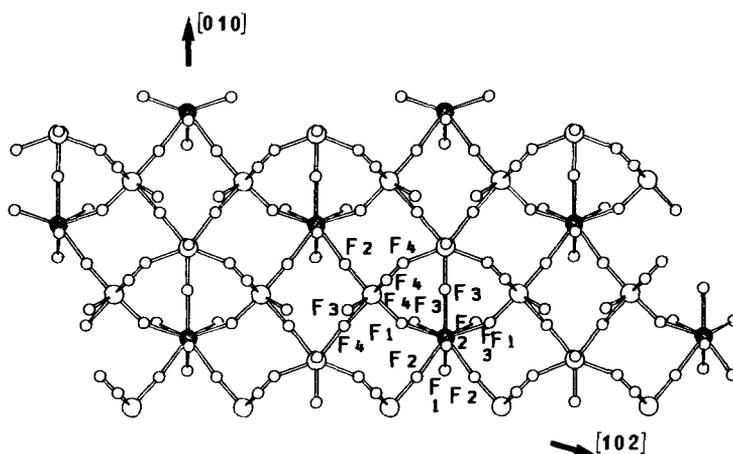

FIG. 4.  $\text{ReO}_3$ -like plane net resulting from the association of adjacent sides of the  $\text{ReO}_3$ -related network of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> structure represented on Fig. 3c: the structure can be entirely described by a stacking of corner-shared identical layers (Fig. 3c showing the connection between two successive sheets). The symbols are the same as on Fig. 1.

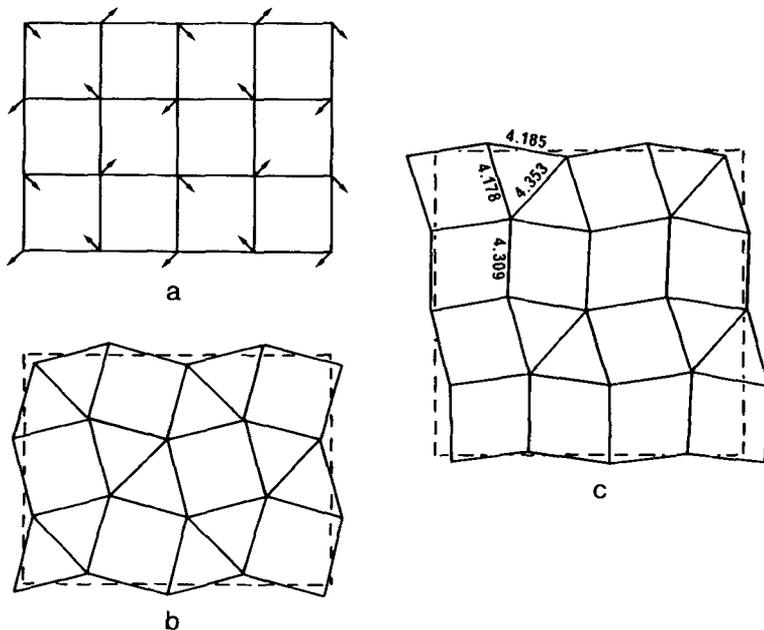

FIG. 5. Structural relation between (a) a  $4^4$  cationic plane net of  $\text{ReO}_3$ ; (b) a  $3^2.4.3.4.$  plane net; and (c) a  $[3.4^3][3^2.4^3]^2$  cationic plane net of  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> (as on Fig. 4 but rotated by  $45^\circ$  in the figure plane). The arrows in (a) represent the direction of rotation of square groups of atoms in the  $\text{ReO}_3$  cationic plane net (or of direct conversion of square faces into triangular ones), transforming this plane net into a  $3^2.4.3.4.$  one.

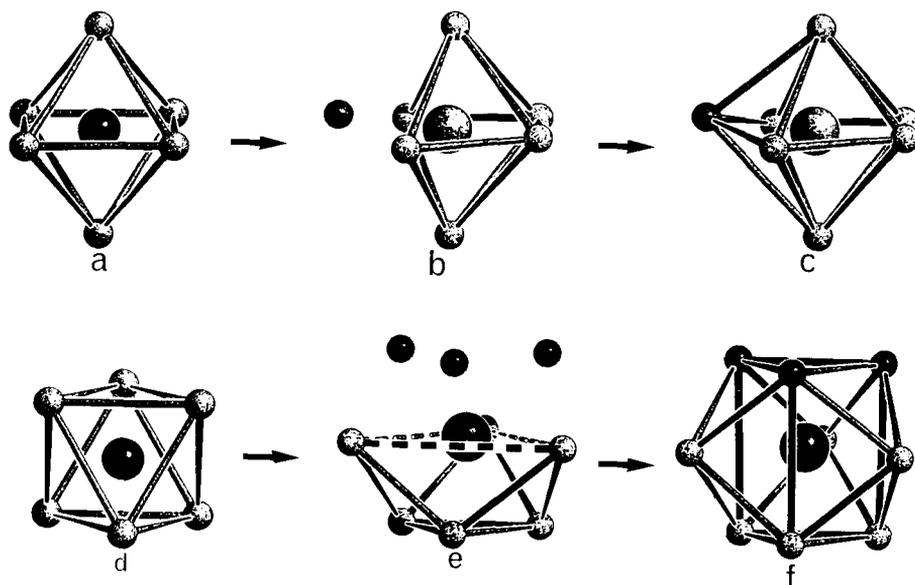

FIG. 6. Transformation of a  $\text{ReO}_3$ -type octahedron, seen along a fourfold axis (a) and along a threefold one (d), respectively into a pentagonal bipyramid (c) by adding one  $\text{F}_3$  excess anion (b), and into a tricapped trigonal prism (f) by adding three  $\text{F}_3$  excess anions (e).

according to the mechanism schematized in Fig. 6; it implies:

for the  $\text{Zr}^{4+}$  polyhedron, the transformation of a basis square face  $\text{F}_4\text{-F}_4\text{-F}_4\text{-F}_4$  (Fig. 6a,b) into a pentagonal  $\text{F}_4\text{-F}_4\text{-F}_4\text{-F}_4\text{-F}_3$  one (Fig. 6c);

for the  $\text{Pr}^{3+}$  polyhedron, the addition of an excess triangular  $\text{F}_3\text{-F}_3\text{-F}_3$  face and, as above described, a correlative shifting of  $\text{Pr}^{3+}$  along the  $Oz$  axis (Fig. 6d,e) from  $z = 0$  to  $z = 0.1717$  ( $1.05 \text{ \AA}$ ) to the center of the T.T.P. so created (Fig. 6f).

Thus,  $\text{Pr}^{3+}$  shifting, particularly evident on Figs. 3a and 3b, is the result of two closely related structural mechanisms:

shortening of Zr-Pr distance by bridging through  $\text{F}_3$  anions; and

regularization of the T.T.P. formed by the addition of three bridging  $\text{F}_3$  anions about each Pr cation.

Such a tendency for cations to shift from the ideal  $\text{ReO}_3$  cationic site toward excess

anions is a general feature of structures deriving from the  $\text{ReO}_3$  type by anion excess and has been previously discussed (15, 16). The cationic shift increases when an  $X$  corner of a  $\text{MX}_6$  octahedron is respectively replaced by an  $X\text{-X}$  edge ( $0.2 \text{ \AA}$  in  $\text{Zr}(\text{F}, \text{O})_{3.33}$ ), by a triangular face ( $0.7 \text{ \AA}$  for Sm in  $\text{SmZrF}_7$ ), and by a square face ( $1.54 \text{ \AA}$  for Ba in  $\beta\text{-BaZr}_2\text{F}_{10}$ ). The direct insertion of a triangular face, transforming an octahedron into a T.T.P., constitutes a new way to introduce an excess of anions into a  $\text{ReO}_3$ -type structure.

A close structural relationship between  $\text{PrZr}_3\text{F}_{15}$  polymorphs has been demonstrated, but this point will be developed in a forthcoming publication.

## Conclusions

Several structures of fluorozirconates of composition lying between  $\text{MF}_3$  and  $\text{MF}_4$  can be derived from the  $\text{ReO}_3$  type through

a mechanism involving cationic ordering (full or partial) and increasing cationic coordination, in order to accommodate excess anions.  $\beta$ -PrZr<sub>3</sub>F<sub>15</sub> is a new original example of this structural family, called anion-excess ReO<sub>3</sub> phases, whose well defined members are mainly SmZrF<sub>7</sub>, Zr(O, F)<sub>3+x</sub>, Bi(Y)Zr<sub>3</sub>F<sub>15</sub>,  $\beta$ -BaZr<sub>2</sub>F<sub>10</sub>, and cubic (Zr, M)F<sub>3+x</sub> phases.

Because of the extreme adaptability of this structure type, numerous phases of various compositions can be related more or less directly to it and will be the subject of further investigation.
