

DEHYDRATION REACTION OF MANGANESE(II) OXALATE DIHYDRATE IN THE SOLID STATE

New method in the study of non-isothermal kinetics

Abstract

A new method was proposed for determining the most probable mechanism function of a solid phase reaction. According to Coats-Redfern's integral equation $E_{\beta \rightarrow 0}$ was calculated by extrapolating β to zero using a series of TG curves with different heating rates. Similarly, $E_{\alpha \rightarrow 0}$ was calculated according to Ozawa's equation. The most probable mechanism function of the solid phase dehydration of manganese(II) oxalate dihydrate was confirmed to be $G(\alpha) = (1-\alpha)^{1/2}$ by comparing $E_{\alpha \rightarrow 0}$ with $E_{\beta \rightarrow 0}$.

Keywords: dehydration, kinetics, manganese(II) oxalate dihydrate, mechanism, non-isothermal, TG-DTA

Introduction

Theoretically, according to Coats-Redfern's integral equation [1] for a sample heated at a definite heating rate (β), if a certain $G(\alpha)$ function gets the best correlation coefficient of $\ln[G(\alpha)/T^2]$ vs. $1/T$ in comparison with those of other $G(\alpha)$ functions, it will be confirmed as the $G(\alpha)$ function of the most probable mechanism function. Actually, in applying this method to a certain solid phase reaction, several $G(\alpha)$ functions often have very similar correlation coefficients, which makes it impossible to select the best one. Therefore, to select the most probable $G(\alpha)$ function some authors put forward a new method by combining integral and differential methods [2] or by combining non-isothermal and isothermal methods [3]. All these methods were conducted at a definite heating rate (β), thus thermal hysteresis would make the system to deviate from the state of equilibrium and the result obtained must be different from the true one. Therefore, it has been proposed to calculate first a series of E corresponding to different heating rates by integration method, then to evaluate $E_{\beta \rightarrow 0}$ by extrapolating β to zero. Theoretically, $E_{\beta \rightarrow 0}$ is the activation energy at thermal equilibrium and the most probable mechanism function $G(\alpha)$ can be confirmed by the criterion

$E_{\beta \rightarrow 0}$. Actually, in applying this method to a certain thermal reaction generally more than one $G(\alpha)$ functions were offered for selection, consequently, the same difficulty was encountered. For overcoming such difficulties the authors believe that the method used in studying homogeneous complex reactions may be applied to study solid phase reactions. For a certain solid phase reaction, $E_{\alpha \rightarrow 0}$ represents the activation energy of the main reaction at the beginning, where secondary reactions do not start yet. Therefore, it can best represent the nature of the reaction. On the basis of $E_{\alpha \rightarrow 0}$, the $E_{\beta \rightarrow 0}$ which fits best to $E_{\alpha \rightarrow 0}$ would be a match for the most probable mechanism function $G(\alpha)$.

Experimental

Manganese oxalate dihydrate was prepared by the usual method. All of the reagents used were of A.R. grade. Powder X-ray diffraction analysis confirmed that the sample was $\text{MnC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$.

The sample was ground and sieved. A definite amount of the sample smaller than 60 mesh was put into the static atmosphere of a Rigaku (Japan) thermal analysis instrument using $\alpha\text{-Al}_2\text{O}_3$ as reference substance. TG-DTA curves were obtained at heating rates of 3, 5, 10 and $15^\circ\text{C min}^{-1}$.

Results and discussion

Typical TG-DTA curves for the title compound at a heating rate of $10^\circ\text{C min}^{-1}$ are shown in Fig. 1. The TG-DTA curves in Fig. 1 indicate that dehydration occurs in one step. The temperature range of dehydration is $113\text{--}150^\circ\text{C}$.

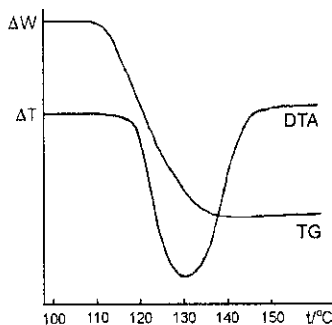

Fig. 1 Typical TG-DTA curves at heating rate: $\beta=10^\circ\text{C min}^{-1}$

The mass loss of 19.94% is in agreement with the theoretical mass loss of 20.11%. Therefore, the dehydration of the sample can be described as

Table 1 Integral forms, $G(\alpha)$ used for the present analysis

No.	Name of function	Mechanism	Symbol	Integral form, $G(\alpha)$
1	Parabolic law	Diffusion, 1D	D ₁	α^2
2	Valensi (Barrer) equation	Diffusion, 2D	D ₂	$(1-\alpha)\ln(1-\alpha)+\alpha$
3	Ginstling-Brounstein equation	Diffusion, 3D (cylindrical symmetry)	D ₃	$(1-2\alpha/3)-(1-\alpha)^{2/3}$
4	Jander equation	Diffusion, 3D (sphere symmetry)	D ₄	$[1-(1-\alpha)^{1/3}]^2$
5	Anti-Jander equation	Diffusion, 3D	D ₅	$[(1+\alpha)^{1/3}-1]^2$

18	Mample power law		P ₄	$\alpha^{1/4}$
19	Second order	Chemical reaction ($n=2$)	C ₂	$(1-\alpha)^{-1}-1$
20	One and one-half order	Chemical reaction ($n=1$ or 1.5)	C _{1/1.5}	$(1-\alpha)^{-1/2}$
21				$1/(1-\alpha)$
22				$1/(1-\alpha)^2$

In order to obtain the kinetic parameters and the most probable mechanism of the dehydration reaction, Coats-Redfern's integral Eq. (1) was employed,

$$\ln \frac{G(\alpha)}{T^2} = \ln \frac{AR}{E\beta} - \frac{E}{RT} \quad (1)$$

where $G(\alpha)$ represents the integral mechanism function (Table 1), α : proportion of mass loss of a sample, i.e.

$$\alpha = \frac{w_0 - w_t}{w_0 - w_\infty}$$

where w_0 , w_t , and w_∞ represent the sample mass at beginning, at $t^\circ\text{C}$ and at the end of dehydration, respectively; β – heating rate ($^\circ\text{C min}^{-1}$), A – pre-exponential factor, R – gas constant, E – apparent activation energy. By substituting the original data listed in Table 2, and all the forms of $G(\alpha)$ in Table 1, into Eq. (1), the corresponding values of E , A in Table 3 are obtained.

Table 3 clearly shows that when samples of the same mass are heated at different heating rates (β), in the course of dehydration reaction function only No. (21) and (20) have the best fit of data and a regularity of thermal decomposition reaction, namely, to have good linear correlation coefficient and kinetic parameters which do not contradict the general rules of thermal decomposition ($E=80\text{--}250 \text{ kJ mol}^{-1}$, $\ln A=16.91\text{--}69.01 \text{ s}^{-1}$) [4]. The above argument has provided an essential basis for determining the probable mechanism of the dehydration reaction. Table 3 also shows that E and $\ln A$ calculated in accordance with a

definite $G(\alpha)$ equation vary regularly with the variation of heating rate. The higher the heating rate, the farther the sample will deviate from equilibrium and the farther the calculated E and $\ln A$ will deviate from their true values. E and $\ln A$ were evaluated by linear regression (for $\beta \neq 0$) or by extrapolation (to $\beta = 0$) and are listed in Table 4.

Table 4 shows that the values of E and $\ln A$ for No. (21) overstepped the general rule of thermal decomposition. Therefore, No. (20), i.e. $G(\alpha) = (1 - \alpha)^{1/2}$ was selected as the kinetic equation of the most probable mechanism with $E = 168.45 \text{ kJ mol}^{-1}$ and $\ln A = 45.40 \text{ s}^{-1}$.

* r – linear correlation coefficient

According to Ozawa's integral equation

$$\log \beta = \log \frac{AE}{Rf(\alpha)} - 2.315 - 0.4567 \frac{E}{RT} \quad (2)$$

where $f(\alpha)$ is the differential expression for a definite reaction mechanism and the others have the same meaning as before.

Equation (2) shows that for a given α , $f(\alpha)$ is constant, $\log \beta$ depends linearly on $1/T$ and the apparent activation energy E for a definite α can be calculated from the slope of the line. For this reason a group of α vs. t curves of different heating rates were drawn using the data in Table 2. The apparent activation ener-

Table 4 Kinetic parameters used for extrapolation of $E_{\beta \rightarrow 0}$

0	168.45	45.4	343.40	100.12

gies E for different α were calculated according to Eq. (2) by employing the α vs. t curves and are listed in Table 5.

The data show that E varies with α , which is due to the complexity of solid phase reactions. $E_{\alpha \rightarrow 0}$ was obtained by extrapolating α to zero (Table 5). The data show that $E_{\alpha \rightarrow 0} = 162.48 \text{ kJ mol}^{-1}$ which is very close to $E_{\beta \rightarrow 0} (= 168.45 \text{ kJ mol}^{-1})$. Therefore, equation No. (20), namely, $G(\alpha = (1-\alpha)^{-1/2})$ is the kinetic equation of the most probable mechanism function of the dehydration reaction.
