Hypotensive Agents. II. Aminoalkyl Esters of Piperidinecarboxylic Acids and Their "Reversed" Ester Derivatives

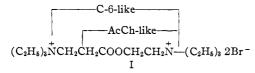

By John H. Biel, Edwin P. Sprengeler and Harris L. Friedman

Received June 10, 1957

The interesting pharmacologic characteristics of β -diethylaminoethyl β -diethylaminopropionate diethobromide, a compound with both ganglionic blocking and muscarinic properties, prompted the synthesis of a number of "cyclic" analogs of this substance. Aminoalkyl and aminoalkynyl esters of the three isomeric N-alkylpiperidine-carboxylic acids were prepared as well as their "reversed" ester derivatives, amino acid esters of N-alkylpiperidyl alcohols. The synthesis of the esters was accomplished by an ester interchange reaction of the aminoalcohol with the methyl ester of the appropriate acid in *n*-heptane and in the presence of catalytic amounts of sodium methoxide; yields ranged from 50–90% of theory. Several of the compounds displayed potent and sustained hypotensive properties when tested in the form of their bis-quaternary ammonium salts in the normotensive dog. The structural features necessary for optimum hypotensive activity are discussed. cussed.

One of the more serious drawbacks of the pres-ent "methonium" hypotensive drugs is the fact that they block both parasympathetic and sympathetic ganglia to an equal extent. Parasympathetic ganglionic blockage results in such undesirable side effects as dry mouth, mydriasis, intestinal atony and urinary retention which in many cases preclude the further use of these agents.

In 1954, an interesting paper appeared by Schueler and Keasling¹ which described the pharma-cologic properties of β -diethylaminoethyl β -diethylaminopropionate diethobromide (I). This com-

pound embodies certain structural features of both acetylcholine (AcCh) and hexamethonium (C-6) and may be looked upon as a ganglionic blocking agent with a "built-in" muscarinic moiety. This postulate was confirmed by the authors who found I to be more potent as a sympathetic blocking agent, the effects of parasympathetic blockage being partially off-set by the post-ganglionic parasympathetic stimulant properties of the compound.

A "cyclic" derivative of acetylcholine, N-methyl-3-piperidyl acetate methiodide (II), had been syn-

thesized earlier by us² and found to be a weak muscarinic agent.8

It was of interest, therefore, to prepare "cyclic" analogs of I as represented by formulas III and IV

(1) F. W. Schueler and H. H. Keasling, J. Am. Pharm. Assoc., 43, 98 (1954).

in the hope of obtaining compounds with more potent and sustained hypotensive properties and a more favorable therapeutic spectrum. Compound IV is a diethylaminoethyl ester of N-ethylnipecotic acid, while the isomeric compound III is the β -diethylaminopropionate ester of N-ethyl-3-hydroxypiperidine or the "reversed" ester of IV.

It was further the object of this work to prepare homologs, position isomers and other congeners of III and IV and study their hypotensive and ganglionic blocking properties. These compounds may be represented by the general structures V and VI where the side chain was linked to the piperidine ring in the 2-, 3- or 4-position.

 R_1 , R_2 and R_3 = alkyl or o-chlorobenzyl

benzyl methylamino

The compounds were conveniently prepared by the ester interchange reaction of a methyl ester with the desired aminoalcohol in normal heptane and in the presence of catalytic amounts of so-dium methoxide, the methanol being removed through a Dean-Stark separator.² The yields ranged from 50–90% of theory.

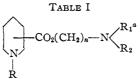

Structure-Activity Relationships .- The base esters were submitted for pharmacologic testing in the form of their quaternary ammonium salts.

The pharmacologic work was carried out under the supervision of Mr. P. A. Nuhfer to whom we are indebted for the hypotensive data.

The compounds were administered intravenously and intraduodenally to the nembutalized, normotensive dog. The structure-activity data of the two more promising series are summarized in Tables IV and V

The following structural features appeared critical to potent and sustained hypotensive activity: (1) The position of the ester side chain, (2) the character and length of the alkylene chain and (3)the N-substituents on the terminal amino group. Thus, the dimethylaminoethyl and morpholino-

ethyl esters of nipecotic acid (nos. 1 and 8) were potent hypotensors while their position isomers (nos. 2 and 9) were inactive. Branching or cyclization of the aminoalkylene side chain (nos. 7, 14 and 15) as well as the introduction of a triple bond (compounds in Table III) abolished hypotensive activity. While an N-o-chlorobenzyl substituent on the side chain (nos. 11, 12 and 24) proved detrimental to hypotensive activity, its introduction into the

piperidine ring yielded some of the most potent hypotensive agents in this series (nos. 25 and 26).

In conclusion we might state that the replacement of an aminoalkyl moiety by a piperidine ring in compounds of the type shown in formula I has yielded several derivatives which are superior to hexamethonium with respect to potency and duration of action. The ganglionic stimulating properties exhibited by the dimethobromide of β -dimeth-

^a N-o-Chlorobenzyl-3-piperidyl instead of N-methyl-3-piperidyl.

ylaminoethyl β -dimethylaminopropionate were not shared by the corresponding cyclic derivative (no. 1 in Table IV). This compound was actually a ganglionic blocking agent. Recently, a paper by Phillips⁴ appeared which described the properties of some dialkylaminoalkyl esters of N-methylnipecotic and N-methylisonipecotic acid. Our data agree with those of Phillips concerning the weak ganglionic blocking activities of the nipecotate esters.

Contrary to the Phillips paper, however, is our finding that the isonipecotate ester (no. 2) is inactive as a hypotensive agent.

filtrates concentrated by vacuum distillation through a 14" column. The residue is subjected to vacuum distillation through a 5" column. The desired aminoalcohol distils as a viscous oil, b.p. $104-106^{\circ}$ (0.1 mm.), yield 56.3 g., (90.8%), n²⁵D 1.5087. 4-Morpholino-2-butynyl N-Methylpipecolinate.—Into a

500-cc. 3-necked round bottom flask equipped with stirrer, reflux condenser, Dean-Stark water separator (CaCl₂ tube) and heating mantle is placed a solution of 31.4 g. (0.20 mole) of methyl N-methylpipecolinate and 31.0 g. (0.20 mole) of 4-morpholino-2-butyn-1-ol in 325 cc. of *n*-heptane; 0.5 g. of NaOMe is added and the mixture refluxed. The methanol produced during the transesterification will separate from the heptane in the water separator. Two additional 0.3-g. portions of NaOMe may be required to complete the reaction. The reaction mixture is concentrated by slowly distilling off approximately 50% of the heptane. The residue is chilled, filtered and the balance of the heptane removed by vacuum distillation through a 14" column. The residue is subjected to vacuum distillation through a 3" column. The desired ester boils at 149–151° (0.25 mm.), yield 41.6 g. (74.3%), n²⁵D 1.5012.

4-Morpholino-2-butynyl N-Methylpipecolinate Dimethobromide.—To a solution of 14.0 g. (0.05 mole) of 4-mor-pholino-2-butynyl-N-methylpipecolinate (0.05 mole) in 80 cc. of isopropyl alcohol is added 19.0 g. (0.20 mole) of methyl bromide. The mixture is refluxed under anhydrous condi-tions for 3 hr. and then chilled. The solid is filtered off and recrystallized from the minimum amount of hot ethanol, m.p. 208-210° dec., yield 20.8 g. (88.5%).

A Kinetic Study of the Ultraviolet Decomposition of Biochemical Derivatives of Nucleic Acid. I. Purines¹

By M. J. KLAND AND L. A. JOHNSON

Received April 16, 1956

Irradiation of purines of biological interest with ultraviolet light under oxygen and nitrogen gives decomposition rates which are zero order between 8×10^{-6} and $5 \times 10^{-4} M$ after an initial "induction" period which is a function of the extent and nature of purine substitution. Decomposition during the induction period follows a square law. For adenine (I) and hypoxanthine (II), decomposition is faster under oxygen, but the breakdown of guanine (III) and xanthine (IV) is inhibited by oxygen as compared with nitrogen.

Sensitivity to ultraviolet (uv.) radiation in purines and pyrimidines may be qualitatively cor-

matographed on Whatman No. 1 filter paper in a descending butanol-water-urea system,⁴ and in butanol-water-ammo-nia (1%).⁵ The presence of one spot at the end of 72 hours related with the number² and position³ of C=O in the former system, and 120 hours in the latter was inter-
