

TABLE I
CONDUCTANCE PARAMETERS FOR Bu_4NBr IN METHANOL AT 25°

Λ_0	\bar{d}	K_A	σ_A
95.31 ± 0.02	2.85 ± 0.02		0.02
95.32 ± 0.02	2.84 ± 0.03		0.03
95.38 ± 0.02	3.2 ± 0.1	2.8 ± 0.6	0.01
95.42 ± 0.01	3.4 ± 0.1	4.3 ± 0.4	0.007

When the data for the nitrobenzene-methanol mixtures² were analyzed by the computer program for associated electrolytes negative \bar{d} or K_A resulted, or the standard deviations of the parameters were larger than the parameters. These data covered too narrow a concentration range for any kind of meaningful interpretation. On the other hand, the data of Witschonke and Kraus⁹ for this salt in pure nitrobenzene had the necessary precision and concentration range. Their data gave $K_A = 56 \pm 3$ and $\bar{d} = 4.9 \pm 0.7$ and $\sigma_A = 0.03$. Thus the \bar{d} is reasonable, the fit is good, and the K_A is large enough so that the assumption of association of this salt in nitrobenzene is justified. When treated as an unassociated electrolyte in nitrobenzene an \bar{d} of 0.12 results which is unreasonably low indicating considerable association.

Considering the above analysis the only experimental result needing explanation is why Bu_4NBr is associated in nitrobenzene and not in methanol or nitromethane¹⁰ although these solvents have about the same dielectric constant. Stabilization of the free ions by solvation will explain the lack of association in methanol, but solvation of the free ions by nitromethane and not by nitrobenzene is unlikely. Hyne's¹ suggestion of an interaction between the nitrobenzene molecule and the Bu_4NBr ion pair is one possible explanation. The dimensions involved could be correct for nitrobenzene but not for nitromethane.

The Enthalpy of Transformation, $\delta\text{-Al}_2\text{O}_3$ to $\alpha\text{-Al}_2\text{O}_3$

Sir:

It is well known that in the oxygen bomb calorimetry of aluminum compounds, a part of the reaction product sometimes occurs in the form of $\delta\text{-Al}_2\text{O}_3$. This is a metastable phase of tetragonal but so far not fully determined structure,¹ whose enthalpy of transformation to the stable form $\alpha\text{-Al}_2\text{O}_3$ (corundum) has not yet been established. As a result, there may be some uncertainty associated with the adopted value of the heat of combustion of aluminum to form Al_2O_3 .²

We have recently become interested in the possible use of high-temperature solution calorimetry for the study of the thermochemistry of certain inorganic solids. Of particular interest to us are solids such as Al_2O_3 , which cannot be dissolved in the common room-temperature

(1) H. P. Rooksby, *J. Appl. Chem.*, **8**, 44 (1958).

solvents. We have found that this oxide dissolves readily in a lead-cadmium borate melt (composition approximately $9\text{PbO} \cdot 3\text{CdO} \cdot 4\text{B}_2\text{O}_3$). Using this solvent we have determined the heats of solution of $\alpha\text{-Al}_2\text{O}_3$ and of $\delta\text{-Al}_2\text{O}_3$ at 705°. For $\alpha\text{-Al}_2\text{O}_3$ we have carried out several determinations with $\alpha\text{-Al}_2\text{O}_3$ of different origin. The mean value of the enthalpy of solution is $+7.6 \pm 0.2$ kcal./mole.

We used two different specimens of $\delta\text{-Al}_2\text{O}_3$ (I and II), both obtained as reaction products in a bomb-calorimetric study of Al_4C_3 .² Duplicate samples of these specimens were dissolved in the same solvent at the considered temperature. The enthalpies of solution were as follows: I, 4.9, 5.0; II, 4.5, 5.1; mean, $+4.9 \pm 0.3$ kcal./mole.

Finally we converted a small sample of $\delta\text{-Al}_2\text{O}_3$ to $\alpha\text{-}$ by heating it for 0.5 hr. at 1450°. The enthalpy of solution of this product was 7.4 kcal./mole, *i.e.*, within the range of the results obtained for the several other samples of $\alpha\text{-Al}_2\text{O}_3$.

Thus we have for the process: $\text{Al}_2\text{O}_3(\delta) = \text{Al}_2\text{O}_3(\alpha)$; $\Delta H^\circ_{978} = -2.7 \pm 0.4$ kcal./mole.

Experimental details of this work will be incorporated in a more extensive study of the various forms of Al_2O_3 and will be published elsewhere.

Acknowledgment.—We are indebted to Drs. G. T. Armstrong and R. C. King of the National Bureau of Standards for providing us with the samples of $\delta\text{-Al}_2\text{O}_3$. This work has been supported in part by the National Science Foundation (GP-1993).

Stereochemistry of the 1,2-Diaminocyclohexane- $\text{N,N}'$ - tetraacetatoaquoferrate(III) Ion,¹ $\text{Fe}(\text{OH}_2)\text{Z}^-$

Sir:

Inasmuch as 1,2-diaminocyclohexane- $\text{N,N}'$ -tetraacetic acid (hereafter DCTA or H_4Z) generally forms more stable complexes² with metal ions than does the closely related ethylenediaminetetraacetic acid (EDTA or H_4Y), one must suppose that the cyclohexane ring of DCTA somehow promotes chelation. It is clear, on the other hand, that the constraints imposed by multiple ring formation must be no less important for chelation by DCTA than by EDTA, and constraints of just this kind are assigned primary responsibility for the unconventional stereochemistry of the sexadentate seven-coordinate aquo complexes, $\text{Fe}(\text{OH}_2)\text{Y}^-$ and $\text{Mn}(\text{OH}_2)\text{Y}^{2-}$, formed by EDTA with $\text{Fe}(\text{III})$ ^{3,4} and Mn -

Fig. 1.—Idealized model in perspective of the hexadentate seven-coordinate aquo complex, $\text{Fe}(\text{OH}_2)\text{Z}^-$, with the twofold axis vertical. The complexed oxygen atoms, O_1 – O_4 , have coordinates measured parallel to the twofold axis from an origin at Fe as follows: O_1 and O_2 , -0.11 Å.; O_3 and O_4 , $+0.56$ Å.

(II).⁵ That both of these conclusions can be valid simultaneously is demonstrated by our determination of structure, using three-dimensional X-ray analysis, of the calcium salt $\text{Ca}[\text{Fe}(\text{OH}_2)\text{Z}]_2 \cdot 9\text{H}_2\text{O}$ containing the anionic Fe(III)–DCTA chelate, $\text{Fe}(\text{OH}_2)\text{Z}^-$.

$\text{Ca}[\text{Fe}(\text{OH}_2)\text{Z}]_2 \cdot 9\text{H}_2\text{O}$ crystallizes in the monoclinic space group $\text{C}2/c$ with $a = 34.34 \pm 0.02$, $b = 8.844 \pm 0.011$, $c = 13.527 \pm 0.017$ Å., $\beta = 91.02 \pm 0.05^\circ$, and a unit cell content of four Ca^{2+} , eight $\text{Fe}(\text{OH}_2)\text{Z}^-$, and thirty-six H_2O . Intensity data, measured by counter methods out to $(\sin \theta)/\lambda = 0.65$ with Mo $K\alpha$ radiation, were utilized in the heavy-atom technique for structure determination. Least-squares refinement of positional and anisotropic thermal parameters gives a residual of 0.094 for the approximately 92% of the data which are definitely above background.

The $\text{Fe}(\text{OH}_2)\text{Z}^-$ ion, as given by the analysis and illustrated in Fig. 1, is a hexadentate seven-coordinate aquo complex which approximates closely to the symmetry required by a twofold axis through OH_2 , Fe, the midpoint of the C–C bond shared by the ethylenediamine and cyclohexane rings, and the midpoint of the opposite C–C bond in the cyclohexane ring. The atoms N_1 , N_2 , Fe, and O of H_2O are coplanar, but O_3 and O_4 are, respectively, -0.99 and $+0.99$ Å. from this plane in positions corresponding to a rotation of 29° about the twofold axis. Consequently, the coordination group of $\text{Fe}(\text{OH}_2)\text{Z}^-$ is geometrically intermediate between the NbF_7^{2-} configuration⁶ which, suitably modified, is utilized⁵ by $\text{Mn}(\text{OH}_2)\text{Y}^{2-}$, and the pentagonal bipyramid which, in an asymmetric form, is utilized³ by $\text{Fe}(\text{OH}_2)\text{Y}^-$. The “chair” form with standard bond parameters is assumed by the cyclohexane ring. Ethylenediamine and glycinate ring

(5) S. Richards, B. Pedersen, J. V. Silverton, and J. L. Hoard, *Inorg. Chem.*, **3**, 27 (1964).

(6) The coordination group about Ca^{2+} in $\text{Ca}[\text{Fe}(\text{OH}_2)\text{Z}]_2 \cdot 9\text{H}_2\text{O}$, comprising five water molecules and two carbonyl oxygen atoms, approximates closely to the idealized (C_{2v} -mm2) NbF_7^{2-} configuration as described by J. L. Hoard, *J. Am. Chem. Soc.*, **61**, 1252 (1939).

geometry in $\text{Fe}(\text{OH}_2)\text{Z}^-$ is very like that in $\text{Mn}(\text{OH}_2)\text{Y}^-$, and is suggestive of slightly more cumulative strain than in $\text{Fe}(\text{OH}_2)\text{Y}^-$. Lengths of the complexing bonds in $\text{Fe}(\text{OH}_2)\text{Z}^-$ conform, nonetheless, to the pattern observed³ in $\text{Fe}(\text{OH}_2)\text{Y}^-$. When averaged in agreement with C_2 -2 symmetry, one obtains $\text{Fe}-\text{O}$ (O_1 and O_2) = 2.017, $\text{Fe}-\text{OH}_2$ = 2.090, $\text{Fe}-\text{O}$ (O_3 and O_4) = 2.092, $\text{Fe}-\text{N}$ = 2.29 Å., all with $\sigma < 0.005$ Å. Passing over differences in detail, we note that the averaged length of the five $\text{Fe}-\text{O}$ bonds comes out just 0.005 Å. larger for $\text{Fe}(\text{OH}_2)\text{Z}^-$ than for $\text{Fe}(\text{OH}_2)\text{Y}^-$, while the comparatively unimportant $\text{Fe}-\text{N}$ bonds are 0.035 Å. shorter in the DCTA complex. Over-all comparisons of the two configurations suggest little or no difference in the energy of complex formation for the DCTA and EDTA chelates.

A principal source of stability² for both chelates is the large increase in entropy associated with the release during chelation of water molecules (five in the present case) from the hydrated $\text{Fe}(\text{OH}_2)_6^{3+}$. The accompanying and partially off-setting decrease in the (partial molar) entropy of the chelating agent is confidently expected to be of lower magnitude for DCTA than for EDTA primarily because the cyclohexane ring in DCTA functions as a relatively severe constraint of the number of configurations available to the free complexing species. The stability constant of $\text{Fe}(\text{OH}_2)\text{Z}^-$ is unreported, but a value of about 10^{27} , as compared with $10^{25.1}$ for $\text{Fe}(\text{OH}_2)\text{Y}^-$, is made plausible by the tabulated data² for the chelates of Mn^{2+} and many other ions.

Kinetics of the Addition of Grignard Reagents to Ketones¹

Sir:

The 1,2-addition of Grignard reagents to carbonyl groups has been the subject of extensive study for many years.² Recently data have been interpreted in terms of the product arising from a low concentration of a complex between a dimeric Grignard reagent and a ketone,^{3,4} from a complex between dialkylmagnesium and ketone,⁵ or from the reaction of a Grignard reagent with a 1:1 complex between a Grignard reagent and a ketone.⁶ In this communication data are presented which are consistent with a mechanism involving product arising from a complex between ketone I and methylmagnesium bromide with an equilibrium constant for complex formation of 6.2 l./mole.

2,4-Dimethyl-4'-methylmercaptobenzophenone (I), m.p. 53 – 54° , displays a strong absorption with λ_{max} 315 $\text{m}\mu$ (ϵ 2.5×10^4) in diethyl ether. An additional band, λ_{max} 360 $\text{m}\mu$, is observed when methylmagnesium
