(30) The occurrence of thls band in the spectra of Ru(II) pyrazinlum complexes provides a satisfactory explanation, within the framework of the trapped-valence model, of the weak shoulder at $\sim 850 \mathrm{~nm}$ In the spectrum of the mlxed valence

Ion (see ref 4). It has been pointed out to us by a referee that owing to the large magnitude of spin-orblt coupllng constants for Ru and Os (G. A. Crosby, K. W. Hipps, and W. H. Elkins, Jr., J. Am. Chem. Soc., 98 , 629 (1974)), there is some doubt In our assignment of the weak, long wavelength transitlons. Our asslgnment does explaln why the weak transitions are observed in $R u(H)$ complexes only when the interaction of
$\pi$ and $\pi^{*}$ orbitals is large and is supported by the fact that the change in $\delta$ is the same whether calculated for Ru(II) or Os(II). For these reasons we prefer to retaln our interpretation though admitting "'tat we may have to revise It when more insight Into the electronic spectra of these specles is galned.
(31) Stmilar behavior is observed in the protonation of

K. Rleder, U. Hauser, H. Slegenthaler, E. Schmidt, A. Ludl, to be submitted to inorg. Chem.
(32) $\alpha_{L}=\left(\pi^{\bullet}|H| \pi^{*}\right), \alpha_{M}=\left(t_{2 g} H \mid t_{2 g}\right), \beta=\left(\pi^{*}|H| t_{2 g}\right)$, and $\delta=\alpha_{L}-\alpha_{M}$.

# Stereochemistry of Eight-Coordinate Mixed-Ligand Complexes of Zirconium. I. Characterization and the Crystal and Molecular Structure of Dinitratobis(acetylacetonato)zirconium(IV)! 

Victor W. Day*2a and Robert C. Fay*2b<br>Contribution from the Departments of Chemistry, Cornell University, Ithaca, New York 14853, and University of Nebraska, Lincoln, Nebraska 68508. Received July 27, 1974

#### Abstract

The crystal and molecular structure of dinitratobis(acetylacetonato)zirconium(IV), $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$, has been determined by single-crystal X -ray diffraction and has been refined (anisotropically on $\mathrm{Zr}, \mathrm{O}, \mathrm{N}$, and C ; isotropically on H ) by least-squares methods to $R_{1}=0.036$ and $R_{2}=0.032$ using 3891 independent diffractometer-recorded reflections having $2 \theta_{\text {MoK } \alpha}<63.7^{\circ}$ and $I>2 \sigma(I)$. The compound crystallizes in the monoclinic space group $C 2 / c$ with eight molecules in a unit cell of dimensions: $a=29.247(3), b=7.870(1), c=14.257(1) \AA ; \beta=93.824(8)^{\circ}\left(\rho_{\text {obsd }}=1.669, \rho_{\text {calcd }}=1.677 \mathrm{~g} /\right.$ $\mathrm{cm}^{3}$ ). The crystal contains discrete eight-coordinate molecules in which bidentate acetylacetonate and bidentate nitrate ligands span the $m$ edges of a (necessarily distorted) $D_{2 d}-\overline{4} 2 m$ dodecahedron; each BAAB trapezoid contains one acetylacetonate and one nitrate ligand. Averaged $\mathrm{Zr}-\mathrm{O}$ bond distances are: $\mathrm{Zr}-\mathrm{O}$ (acac) $2.096 \AA$ and $\mathrm{Zr}-\mathrm{O}$ (nitrate) $2.295 \AA$. Within a particular chelate ring, the $\mathrm{Zr}-\mathrm{O}$ bond lengths involving dodecahedral A sites exceed those involving B sites by $0.015-0.051$ $\AA(5 \sigma-17 \sigma)$ and these differences appear to be propagated in the $\mathrm{N}-\mathrm{O}$ and $\mathrm{C}-\mathrm{O}$ bond lengths in the ligands, $\mathrm{N}-\mathrm{O}_{\mathrm{A}}$ being shorter than $\mathrm{N}-\mathrm{O}_{\mathrm{B}}$ by $0.012-0.019 \AA(3 \sigma-5 \sigma)$ and $\mathrm{C}-\mathrm{O}_{\mathrm{A}}$ being shorter than $\mathrm{C}-\mathrm{O}_{\mathrm{B}}$ by $0.017-0.023 \AA(4 \sigma-6 \sigma)$. The ligands are planar, and the acetylacetonate methyl groups adopt a conformation in which one methyl hydrogen atom and the $-\mathrm{C} H=$ hydrogen atom are eclipsed. The relative merits of the observed $C_{2}-m m m m$ stereoisomer and other possible stereoisomers are discussed in terms of ligand bite, polyhedral edge lengths, and nonbonded contacts. In solution, $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ is a monomeric nonelectrolyte which is stereochemically nonrigid on the NMR time scale at temperatures above $-130^{\circ}$. Below $-144^{\circ}$, stereochemical rearrangement is slow, and ${ }^{1} \mathrm{H}$ NMR spectra are consistent with the $C_{2}-m m m m$ structure found in the solid state. Retention of coordination number eight in solution is indicated by the similarity of solid-state and solutionstate infrared spectra.

In 1958 Brainina and coworkers ${ }^{3}$ reported syntheses of the interesting, mixed-ligand zirconium complexes, Zr (dik) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ and $\mathrm{Zr}(\mathrm{dik})_{3}\left(\mathrm{NO}_{3}\right)$, where dik represents the anion of acetylacetone or benzoylacetone. More recently some analogous hafnium complexes have been prepared. ${ }^{4}$ These compounds have not yet been fully characterized, and nothing is known about their structures.

Structural points of interest include (1) the denticity of the nitrate ligands and the coordination number ( CN ) of the zirconium atom and (2) the geometry of the coordination polyhedron. For the dinitrato complexes, possible structures are $\mathrm{Zr}(\mathrm{dik})_{2}\left(\mathrm{ONO}_{2}\right)_{2}(\mathrm{CN} 6), \mathrm{Zr}(\mathrm{dik})_{2}\left(\mathrm{O}_{2} \mathrm{NO}\right)(\mathrm{O}-$ $\mathrm{NO}_{2}$ ) (CN 7), and $\mathrm{Zr}(\mathrm{dik})_{2}\left(\mathrm{O}_{2} \mathrm{NO}\right)_{2}$ (CN 8), depending on the mode of nitrate attachment. ${ }^{5}$ In addition to analogous structures for the mononitrato complexes, viz., Zr (dik) $)_{3}\left(\mathrm{ONO}_{2}\right)(\mathrm{CN} 7)$ and $\mathrm{Zr}(\mathrm{dik})_{3}\left(\mathrm{O}_{2} \mathrm{NO}\right)(\mathrm{CN} \mathrm{8})$, one must also consider an ionic structure, $\left[\mathrm{Zr}(\mathrm{dik})_{3}\right]^{+}\left[\mathrm{NO}_{3}\right]^{-}$, in which the zirconium atom exhibits CN 6 .

Structures of the nitrato complexes are of interest in relation to previous structural work on halo(acetylaceton-
ato)zirconium complexes and the tetrakisacetylacetonate. $\mathrm{Zr}(\mathrm{acac})_{3} \mathrm{Cl}$ is a pentagonal bipyramidal molecule (CN 7), ${ }^{6}$ while $\mathrm{Zr}(\mathrm{acac})_{4}$ adopts a square antiprismatic geometry (CN 8). ${ }^{7}$ The detailed geometry of $\mathrm{Zr}(\mathrm{acac})_{2} \mathrm{Cl}_{2}$ is not yet known; however, NMR, infrared, Raman, and dipole moment studies point to a cis octahedral structure in solution. ${ }^{8}$

In this paper we report the characterization and the crystal and molecular structure of dinitratobis(acetylacetonato) zirconium(IV), $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$. A following paper will deal with $\mathrm{Zr}(\mathrm{acac})_{3}\left(\mathrm{NO}_{3}\right)$.

## Experimental Section

Preparation and Physical Data. Dinitratobis(2,4-pentanedionato) zirconium(IV), $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$, was prepared in $63 \%$ yield according to the procedure of Brainina et al. ${ }^{3}$ by reaction of acetylacetone with $\mathrm{ZrO}\left(\mathrm{NO}_{3}\right)_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ in benzene solution. Recrystallization from hot benzene-hexane ( $\sim 40: 60 \mathrm{v} / \mathrm{v}$ ), under a dry nitrogen atmosphere, gave colorless crystals which were washed with dry hexane and dried in vacuo for 12 hr at room temperature: mp 149-151 ${ }^{\circ}$, lit. ${ }^{3} 146-148^{\circ}$; mol wt 392 (cryoscopic, 0.0327 m nitro-
benzene solution), calcd 413; molar conductance $0.63 \mathrm{ohm}^{-1} \mathrm{~cm}^{2}$ $\mathrm{mol}^{-1}\left(1.00 \times 10^{-3} \mathrm{M}\right.$ nitrobenzene solution, $25.0^{\circ}$ ); NMR $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ solution, $\left.10.0 \mathrm{~g} / 100 \mathrm{ml}, 37^{\circ}\right):-2.12\left(\mathrm{CH}_{3}\right)$ and -5.93 $\mathrm{ppm}(-\mathrm{CH}=)$ relative to an internal reference of tetramethylsilane ( $1 \%$ by volume); ir $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right.$ solution) $\nu_{\mathrm{s}}(\mathrm{C}-\mathrm{O}) 1557 \mathrm{~cm}^{-1}$ and $\nu_{\mathrm{as}}(\mathrm{C}-\mathrm{O}) 1353 \mathrm{~cm}^{-1}$.

Crystallography. Single crystals of $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$, suitable for X-ray work, were grown from a dichloromethane-hexane mixture and were sealed under nitrogen in thin-walled glass capillaries for all subsequent X-ray studies. Weissenberg and precession photographs used to determine the probable space group and a preliminary set of lattice constants indicated monoclinic, $2 / \mathrm{m}$, symmetry. The systematically absent reflections were those required by space group $C c-C_{s}^{4}$ (No. 9) or $C 2 / c-C_{2 h}{ }^{6}$ (No. 15). The choice of the centrosymmetric space group, $C 2 / c$, was fully supported by the negative results of sensitive tests for piezoelectricity made with a Geibe-Schiebe detector and by all stages of the subsequent structure determination. Use of the accurate lattice constants given below for a unit cell containing eight $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ molecules gave a calculated density of $1.677 \mathrm{~g} / \mathrm{cm}^{3}$, in excellent agreement with the observed density of $1.669 \mathrm{~g} / \mathrm{cm}^{3}$ measured by flotation in a mixture of hexane, carbon tetrachloride, and 1,1,2,2-tetrabromoethane.

The simple atomic arrangement in the crystal was determined by the straightforward application of the heavy-atom technique using photographically recorded and three-dimensionally correlated diffraction data whose intensities were visually estimated by comparison with a "standard" intensity strip. Twenty-four interpenetrating layers of equiinclination Weissenberg intensity data, 9 along $b$ and 15 along $c$, were recorded using multiple-film techniques with Zr -filtered $\mathrm{Mo} \mathrm{K} \bar{\alpha}$ radiation. The visually estimated intensities were reduced to relative squared amplitudes, $\left|F_{0}\right|^{2}$, by means of standard Lorentz and polarization factors. The 2356 independent data which resulted from the three-dimensional correlation of the relative $\left|F_{0}\right|^{2}$ values were used to calculate a Patterson synthesis, from which the Zr atom was located. A single difference Fourier synthesis at this point was sufficient to locate all remaining non-hydrogen atoms of the totally general-position asymmetric unit. Unit-weighted block-diagonal least-squares refinement employing anisotropic thermal parameters for all non-hydrogen atoms resulted in a conventional unweighted residual

$$
R_{1}=\Sigma\left\|F_{\mathrm{o}}\left|-\left|F_{\mathrm{c}} \| / \Sigma\right| F_{\mathrm{o}}\right|\right.
$$

of 0.091 . Bond lengths and angles calculated from the refined structural parameters at this point indicated CN 8 for the Zr atom with each bidendate ligand spanning an $m$ edge of a (necessarily distorted) $D_{2 d}$ dodecahedron. ${ }^{9}$ Although the $\mathrm{Zr}-\mathrm{O}$ bonds to A-site oxygen atoms were systematically longer than those to B -site oxygen atoms within the same ligand (see Figure 1), the differences were not statistically significant since the estimated standard deviation in an individual $\mathrm{Zr}-\mathrm{O}$ bond length averaged $0.010 \AA$. It was therefore decided to re-collect a set of diffractometer data in the hope that a more complete and accurate set of diffraction data might enable us to better characterize these and other subtle differences existing among the various bonds.

A nearly cube-shaped specimen, 0.50 mm on an edge, of Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ was cut from a larger single crystal in a glove bag under nitrogen and sealed in a thin-walled glass capillary and then very carefully aligned optically on a computer-controlled four-circle Syntex $P_{i}$ autodiffractometer. A total of 15 high-angle ( $2 \theta_{\text {Moкā }}$ $>35^{\circ}$ ) reflections, chosen to give a good sampling of reciprocal space and diffractometer settings, were used to align the crystal and calculate angular settings for each reflection. A least-squares refinement of the diffraction geometry for these 15 reflections, recorded at the ambient laboratory temperature of $20 \pm 1^{\circ}$ with Nb -filtered Mo $\mathrm{K} \bar{\alpha}$ radiation ( $\lambda 0.71069 \AA$ ), gave the lattice constants $a=29.247 \pm 0.003 \AA, b=7.870 \pm 0.001 \AA, c=14.257 \pm$ $0.001 \AA$, and $\beta=93.824 \pm 0.008^{\circ}$.

Intensity measurements utilized Nb -filtered $\mathrm{Mo} \mathrm{K} \bar{\alpha}$ radiation and the $\theta-2 \theta$ scanning technique with a $3^{\circ}$ takeoff angle and a nor-mal-focus X -ray tube. A scanning rate of $3^{\circ} / \mathrm{min}$ was employed for the scan between $2 \theta$ settings $1.0^{\circ}$ above and below the calculated $K \alpha$ doublet values ( $\lambda_{K_{\alpha}} 0.70926 \AA$ and $\lambda_{K \alpha_{2}} 0.71354 \AA$ ) of each reflection. Background counts, each lasting for half the total scan time, were taken at both ends of the scan range. A total of

5650 reflections having $2 \theta_{\text {MoK }}<63.7^{\circ}$ ( 1.5 times the number of data in the limiting $\mathrm{CuK} \bar{\alpha}$ sphere) were measured in concentric shells of increasing $2 \theta$ containing approximately 1900 reflections each. Six standard reflections, monitored every 300 reflections, gave no indication of misalignment and/or deterioration of the crystal.

The linear absorption coefficient of the crystal ${ }^{10}$ for Mo $\mathrm{K} \bar{\alpha}$ radiation is $0.72 \mathrm{~mm}^{-1}$, yielding a $\mu R$ of 0.22 for a spherical crystal having the same volume as the cube-shaped specimen actually used. Since the absorption of X-rays by a spherical crystal having $\mu R=0.22$ is virtually independent of scattering angle, ${ }^{11}$ and deviations from this absorption occasioned by the use of the cubeshaped specimen are practically negligible except for a trivial fraction of the reflections, no absorption corrections were made and the intensities were reduced to relative squared amplitudes, $\left|F_{0}\right|^{2}$. by means of standard Lorentz and polarization corrections.

Of the 5650 reflections examined, 1759 were rejected as objectively unobserved by applying the rejection criterion, $I<2.0 \sigma(I)$, where $\sigma(I)$ is the standard deviation in the intensity computed from

$$
\sigma^{2}(I)=\left(C_{1}+k^{2} B\right)
$$

$C_{1}$ being the total count from scanning, $k$ the ratio of scanning time to total background time (in this case, $k=1$ ), and $B$ the total background count. The remaining 3891 observed intensities were used to locate the hydrogen atoms and refine the structure.

Unit-weighted anisotropic full-matrix least-squares refinement to convergence of the structural parameters for the 23 non-hydrogen atoms followed by a difference Fourier synthesis permitted the location of all 14 hydrogen atoms in the asymmetric unit. Further cycles of unit-weighted full-matrix least-squares minimization of the function $\Sigma w\left(\left|F_{0}\right|-K\left|F_{\mathrm{c}}\right|\right)^{2}$ (where $K$ is the scale factor), which employed isotropic thermal parameters for hydrogen atoms and anisotropic thermal parameters for all other atoms, led to $R_{1}$ $=0.036$ and a conventional weighted residual

$$
R_{2}=\left\{\Sigma w\left(\left|F_{0}\right|-K\left|F_{\mathrm{o}}\right|\right)^{2} / \Sigma w\left|F_{\mathrm{o}}\right|^{2}\right\}^{1 / 2}
$$

of 0.038 for 3891 reflections. These and all subsequent refinement cycles employed anomalous dispersion corrections for the Zr atom ${ }^{12}$ and a least-squares refineable extinction correction of the form $1 /\left(1+g I_{c}\right)^{1 / 2}$ (where the extinction coefficient, $g$, refined to a final value of $3.24 \times 10^{-7}$ ). Empirical weights ( $w=1 / \sigma^{2}$ ) were then calculated from

$$
\begin{aligned}
\sigma=\sum_{0}^{3} a_{\mathrm{n}}\left|F_{\mathrm{o}}\right|^{n}= & 1.82-0.154 \times 10^{-1}\left|F_{\mathrm{o}}\right|+ \\
& 0.440 \times 10^{-4}\left|F_{\mathrm{o}}\right|^{2}+0.261 \times 10^{-6}\left|F_{\mathrm{o}}\right|^{3}
\end{aligned}
$$

the $a_{\mathrm{n}}$ being coefficients derived from the least-squares fitting of the curve

$$
\left\|F_{\mathrm{o}}|-K| F_{\mathrm{c}}\right\|=\sum_{0}^{3} a_{\mathrm{n}}\left|F_{\mathrm{o}}\right|^{n}
$$

where the $F_{\mathrm{c}}$ values were calculated from the fully refined model using unit weighting. The final cycles of least-squares refinement utilized these weights to refine hydrogen atoms isotropically and all other atoms anisotropically together with the scale factor and extinction coefficient to give final values of 0.036 and 0.032 for $R_{1}$ and $R_{2}$, respectively, for 3891 independent reflections. During the final cycle of refinement, no parameter shifted by more than $0.40 \sigma$, with the average shift (including shifts for hydrogen atoms) being $0.03 \sigma$. The final parameters from least-squares cycles utilizing the empirical weights did not differ significantly from the final parameters from cycles utilizing unit weights. The atomic form factors compiled by Cromer and Mann ${ }^{13}$ were used in all structure factor calculations.

The following programs were used on an IBM $360 / 65$ computer for this work: MAGTAPE, SCALELP, and SCTFT2, data reduction programs written by V. W. Day; FORDAP, Fourier and Patterson synthesis program, a modified version of A. Zalkin's original program; ORFLSE, full-matrix lease-squares structure refinement program, a highly modified version of Busing, Martin, and Levy's original ORFLS; ORFFE, bond lengths and angles with standard deviations by Busing. Martin, and Levy; ORTEP2, thermal ellipsoid

## Results and Discussion

Structure in the Solid State. Final atomic coordinates and thermal parameters for crystalline $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ are presented in Tables I-III. ${ }^{14}$ A model seen in perspective of the contents of the asymmetric unit specified by the atomic
coordinates of Tables I and III is illustrated in Figure 2; each non-hydrogen atom is represented by an ellipsoid having the shape, orientation, and relative size concomitant with the thermal parameters listed in Table II (hydrogen atoms are represented by small spheres not representative of their true thermal motion).

The crystal contains discrete eight-coordinate molecules in which bidentate acetylacetonate and bidentate nitrate ligands span the $m$ edges (see Figure 1) of a (necessarily distorted) $D_{2 d}-\overline{4} 2 m$ dodecahedron. Each BAAB trapezoid contains one acetylacetonate and one nitrate ligand; thus the approximate molecular point group symmetry is $C_{2}-2$, the quasi-twofold axis passing through the midpoints of the opposite $b$ edges (Figure 1) which connect atoms $\mathrm{O}_{\mathrm{a} 2}$ and $\mathrm{O}_{\mathrm{b} 2}$ and atoms $\mathrm{O}_{\mathrm{c} 2}$ and $\mathrm{O}_{\mathrm{d} 2}$ (Figure 2). Note that the atom numbering system reflects the quasi-twofold symmetry; for example, oxygen atoms which occupy dodecahedral A sites of Figure 1 have the numerical subscript 1 in Figure 2 while those which occupy B sites have the numerical subscript 2 . Bond distances, polyhedral edge lengths, and bond angles in the $\mathrm{ZrO}_{8}$ coordination group are presented in Tables IV and V. A perspective view (adapted from a computer-drawn diagram) of the coordination polyhedron is shown in Figure 3. Average polyhedron-shape parameters are compared with theoretical values in Table VI. The packing of Zr (acac) $\mathbf{2}_{2}\left(\mathrm{NO}_{3}\right)_{2}$ molecules in the crystal is depicted in Figure 4. There are no unusually short intermolecular contacts.

In terms of the geometric criteria discussed by Lippard and Russ, ${ }^{15}$ the choice of coordination polyhedron for Zr (acac) $\mathbf{2}_{2}\left(\mathrm{NO}_{3}\right)_{2}\left(D_{2 d}-\overline{4} 2 m\right.$ dodecahedron or $D_{4 d}-\overline{8} 2 m$ square antiprism) is unambiguous. The angle between the two intersecting trapezoidal best planes defined by atoms $\mathrm{Zr}, \mathrm{O}_{\mathrm{a} 1}$, $\mathrm{O}_{\mathrm{a} 2}, \mathrm{O}_{\mathrm{c} 1}$, and $\mathrm{O}_{\mathrm{c} 2}$ and by atoms $\mathrm{Zr}, \mathrm{O}_{\mathrm{b} 1}, \mathrm{O}_{\mathrm{b} 2}, \mathrm{O}_{\mathrm{d} 1}$, and $\mathrm{O}_{\mathrm{d} 2}$ (Table IX) is $90.7^{\circ}$ vs. $90.0^{\circ}$ for a perfect dodecahedron and $77.4^{\circ}$ for a perfect antiprism. Values of $d_{\mathrm{T}}$, the average displacement of ligand atoms from the trapezoidal best planes, are 0.04 and $0.05 \AA$, respectively ( $0.0 \AA$ for a perfect dodecahedron), while values of $d_{\mathrm{S}}$, the average displacement of ligand atoms from the best planes through the

$a$ Figures in parentheses are estimated standard deviations in the last significant figure. $b$ Oxygen atoms carry a literal subscript to identify the particular ligand ( $a, b, c$, or $d$ ) and a numerical subscript to distinguish between atoms of the same ligand. Oxygen atoms occupy ing dodecahedral A sites of Figure 1 have the numerical subscript 1 while those occupying $B$ sites have the numerical subscript 2. Atoms are labeled in agreement with Figure 2 and Tables I and II. $c$ The numbers in parentheses following each averaged value are the root mean square estimated standard deviation for an individual datum and the mean and maximum deviation from the average value.
two "square faces" of the "antiprism", are 0.27 and 0.23 $\AA^{16}$ ( $0.0 \AA$ for a perfect antiprism).

Distortion of the $\mathrm{ZrO}_{8}$ dodecahedron from full $D_{2 d}-\overline{4} 2 m$ symmetry is necessitated by the chemical nonequivalence of the ligands and is most evident in the $\mathrm{Zr}-\mathrm{O}$ bond distances and in the lengths of the $m$ edges. The $\mathrm{Zr}-\mathrm{O}$ (acac) bonds are $\sim 0.20 \AA$ shorter (and are presumably stronger and more covalent) than the $\mathrm{Zr}-\mathrm{O}\left(\mathrm{NO}_{3}{ }^{-}\right)$bonds (cf. Table IV), and the $m$ edges spanned by the acetylacetonate ligands are $\sim 0.52 \AA$ longer than those spanned by the nitrate ligands (cf. Table $V$ and Figure 3). The length of an $m$ edge corresponds to the "bite" of the ligand and is determined primarily by the ligand geometry and the number of atoms in the metal-chelate ring. Other polyhedral edges of the same class ( $a, b$, or $g$ ) have rather similar lengths (cf. Table V). Mean plane calculations on the trapezoidal planes defined by the ligand oxygen atoms (i.e. Zr atom excluded; cf . Table IX) indicate that the inequality between the Zr O (acac) and $\mathrm{Zr}-\mathrm{O}\left(\mathrm{NO}_{3}{ }^{-}\right)$bonds is associated with small

Figure 1, The $D_{2 d}-\overline{4} 2 m$ dodecahedron, with vertices and edges labeled according to Hoard and Silverton. ${ }^{9}$ Equivalent trapezoids, BAAB, lie in the mutually perpendicular mirror planes and interlock in agreement with $\overline{4}$. The ligand $A$ sites and $B$ sites are located, respectively, at the corners of two nonequivalent, interpenetrating $D_{2 d}-42 m$ tetrahedra. the A -site tetrahedron being elongated along the $\overline{4}$ axis and the B -site tetrahedron being compressed along the $\overline{4}$ axis. The 18 dodecahedral edges are distributed among four classes: $a$ (2), $b$ (4), $m$ (4), and $g$ (8). Each of the two mutually perpendicular twofold axes passes through the midpoints of a pair of opposite $b$ edges.

Figure 2, Model in perspeclive of the $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ molecule. The quasi-twofold axis passes midway between atoms $\mathrm{O}_{\mathrm{a} 2}$ and $\mathrm{O}_{\mathrm{b} 2}$ and aloms $\mathrm{O}_{\mathrm{c} 2}$ and $\mathrm{O}_{\mathrm{d} 2}$.
displacements of the Zr atom from these trapezoidal planes in the direction of the acetylacetonate ligands; thus the Zr atom is displaced $0.19 \AA$ from the mean plane defined by atoms $\mathrm{O}_{\mathrm{a} 1}, \mathrm{O}_{\mathrm{a} 2}, \mathrm{O}_{\mathrm{c} 1}$, and $\mathrm{O}_{\mathrm{c} 2}$ (displacement toward acac ligand b) and $0.09 \AA$ from the mean plane defined by atoms $\mathrm{O}_{\mathrm{b} 1}, \mathrm{O}_{\mathrm{b} 2}, \mathrm{O}_{\mathrm{d} 1}$, and $\mathrm{O}_{\mathrm{d} 2}$ (displacement toward acac ligand a). The averaged $\mathrm{Zr}-\mathrm{O}(\mathrm{acac})$ bond length ( $2.096 \AA$ ) is shorter than the averaged $\mathrm{Zr}-\mathrm{O}$ bond lengths in the eight- , coordinate $\mathrm{Zr}(\mathrm{acac})_{4}\left(2.198 \AA\right.$ ). ${ }^{7}$ seven-coordinate Zr (acac) ${ }_{3} \mathrm{Cl} \quad(2.129 \AA){ }^{6}$ and pseudo-six-coordinate $(\pi$ $\left.\mathrm{C}_{5} \mathrm{H}_{5}\right) \mathrm{Zr}(\mathrm{acac})_{2} \mathrm{Cl}(2.15 \AA) .{ }^{17}$ This suggests that Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ could be regarded as a pseudo-octahedral, six-coordinate complex with each nitrate ligand being considered to occupy only one coordination site. ${ }^{18}$ Alternatively, the $\mathrm{Zr}-\mathrm{O}$ (acac) bonds may simply be shortened at the expense of the $\mathrm{Zr}-\mathrm{O}\left(\mathrm{NO}_{3}^{-}\right)$bonds since the averaged

Figure 3, Perspective view (adapted from a computer-drawn diagram) of the dodecahedral coordination polyhedron as observed in the Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ molecule. The four short edges of length $2.124,2.132$, 2.635 , and $2.653 \AA$ are the dodecahedral $m$ edges spanned by the four bidentate ligands.

Figure 4. Model in perspective to illustrate the packing of Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ molecules in the crystalline arrangement. The contents of one unit cell are viewed normal to the (010) plane.
length of all eight $\mathrm{Zr}-\mathrm{O}$ bonds in the $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ $(2.195 \AA)$ is nearly identical with the averaged $\mathrm{Zr}-\mathrm{O}$ bond length in $\mathrm{Zr}(\mathrm{acac})_{4}$.

It will be noted from Table IV that the $\mathrm{Zr}-\mathrm{O}$ bonds directed toward the dodecahedral A sites (Figure 1), $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$, are significantly longer than the bonds directed toward the B sites, $\mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$. This is the case for all four ligands, the difference between $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$ and $\mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$ ranging from $0.015 \AA$ $(5 \sigma)$ to $0.051 \AA(17 \sigma)$. Similar differences in the $\mathrm{M}-\mathrm{L}_{\mathrm{A}}$ and $\mathrm{M}-\mathrm{L}_{\mathrm{B}}$ bond distances have been observed for $\mathrm{Zr}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{4}{ }^{4-}$ $(\sim 0.06 \AA)^{19}$ and $\mathrm{Ti}\left(\mathrm{S}_{2} \mathrm{CNEt}_{2}\right)_{4}(\sim 0.08 \AA),{ }^{20}$ which also have an mmmm dodecahedral structure. The ratio of the averaged bond distances, $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}} / \mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$, in Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ is 1.015 , compared with 1.00 for the hard sphere model and 1.03 for the $D_{2 d}-\overline{4} 2 m$ dodecahedron which minimizes closed-shell ligand repulsions. ${ }^{9}$ Relative lengthening of the $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$ bonds reduces $\mathrm{O}_{\mathrm{A}} \cdots \mathrm{O}_{\mathrm{A}}$ ligand repulsions along the $a$ edges, the shortest of the polyhedral edges not spanned by a bidentate ligand (Table V). It is possible, as suggested by Colapietro et al. for $\mathrm{Ti}\left(\mathrm{S}_{2} \mathrm{C}\right.$ $\left.\mathrm{NEt}_{2}\right)_{4},{ }^{20}$ that $\pi$ bonding ( $\mathrm{O}_{\mathrm{B}} \pi \rightarrow \mathrm{Zr} \mathrm{d}_{x^{2}-y^{2}}$ ) may also contribute to the difference between the $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$ and the $\mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$ bond lengths. In this connection it is interesting to note (Table IV) that the difference in bond lengths is greater for the $\mathrm{Zr}-\mathrm{O}$ (acac) bonds than for the $\mathrm{Zr}-\mathrm{O}\left(\mathrm{NO}_{3}{ }^{-}\right)$ bonds.

Table V. Polyhedral Edge Lengths and Bond Angles Subtended at the $\mathrm{Zr}(\mathrm{IV})$ Atom in the Coordination Group of $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}{ }^{a}$

| $\mathrm{Zr}_{-\mathrm{O}_{\mathrm{A}} / \mathrm{Zr}-\mathrm{O}_{\mathrm{B}}}$ | 1.015 | 1.03 | 1.00 |

$a_{a, b, m}$, and $g$ are averaged lengths of the dodecahed ral edges (Figure 1) in units of the averaged $\mathrm{Zr}-\mathrm{O}$ bond distance ( $2.195 \AA$ ). $\theta_{\mathrm{A}}$ and $\theta_{\mathrm{B}}$ are the averaged angles which the $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$ and $\mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$ bonds, respectively, make with the $\overline{4}$ axis (Figure 1). $b$ Most favorable coordination polyhedron, calculate ${ }^{9}$ to minimize the closed-shell ligand repulsive energy. $c$ Hard sphere model.

Mixed-ligand chelates of the type $\mathrm{M}(\mathrm{XX})_{2}(\mathrm{YY})_{2}$ which adopt dodecahedral stereochemistry with an mmmm wrapping pattern may exist as two geometric isomers: (1) a $C_{2 v}$ isomer in which the $m$ edges of each BAAB trapezoid (Figure 1) are spanned by ligands of the same type; i.e., both XX ligands are on one trapezoid, and both YY ligands are on the other, or (2) a $C_{2}$ isomer in which the $m$ edges of each trapezoid contain one XX ligand and one YY ligand. The latter stereoisomer is observed in crystalline Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ and is expected to be the more stable isomer whenever there is an appreciable difference between the

$a$ Numbers in parentheses are estimated standard deviations in the last significant figure. $b$ The numbers in parentheses following each averaged value are the root mean square estimated standard deviation for an individual datum and the mean and maximum deviation from the average value. $c$ The bite of the ligand.
bites of XX and $\mathrm{YY}^{21}$ A $C_{2 v}$ structure for Zr (acac) $)_{2}\left(\mathrm{NO}_{3}\right)_{2}$ would require that nonbonded contacts along the $g$ edges decrease from the observed values (Table V) of $2.68-2.87 \AA$ (av $2.78 \AA$ ) to a value of $\sim 2.67 \AA{ }^{22}$ It appears that the relatively large bite of the acetylacetonate ligand does not permit two acac ligands to be located on the same trapezoid of a $\mathrm{ZrO}_{8}$ dodecahedron; this view is supported by the fact that $\mathrm{Zr}(\mathrm{acac})_{3}\left(\mathrm{NO}_{3}\right)$ shuns the mmmm wrapping pattern in favor of the previously unobserved dodecahedral abmg arrangement ${ }^{23}$ and $\mathrm{Zr}(\mathrm{acac})_{4}$ deserts the dodecahedron (almost entirely) in favor of a square antiprism. ${ }^{7}$ Among the dodecahedral stereoisomers enumerated by Hoard and Silverton ${ }^{9}$ are two ( $a a b b$ and $m m g g$ ) which may allow optimum matching of ligand bites and polyhedral edge lengths for complexes of the type $\mathrm{M}(\mathrm{XX})_{2}(\mathrm{YY})_{2}$. In the case of $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$, the $m m g g$ isomer, with acac ligands on the $g$ edges, is not obviously inferior to the observed mmmm isomer; however, the $a a b b$ isomer, with $\mathrm{NO}_{3}{ }^{-}$ligands on the $a$ edges, ${ }^{24}$ is disfavored because the bite of the acac ligand (generally 2.6-2.9 $\AA^{25}$ ) is too short to properly span the $b$ edges $(\sim 3.16 \AA)$.

Bond lengths and angles within the acetylacetonate and nitrate ligands are presented in Tables VII and VIII, respectively, and the results of mean plane calculations on the ligands are included in Table IX. It is noteworthy that the differences between the $\mathrm{Zr}-\mathrm{O}_{\mathrm{A}}$ and $\mathrm{Zr}-\mathrm{O}_{\mathrm{B}}$ bond lengths (Table IV) appear to be propagated in the $\mathrm{C}-\mathrm{O}$ and $\mathrm{N}-\mathrm{O}$ bond lengths in the ligands, $\mathrm{C}-\mathrm{O}_{\mathrm{A}}$ being shorter than $\mathrm{C}-\mathrm{O}_{\mathrm{B}}$ by 0.017-0.023 $\AA(4 \sigma-6 \sigma)$ and $\mathrm{N}-\mathrm{O}_{\mathrm{A}}$ being shorter than
$\mathrm{N}-\mathrm{O}_{\mathrm{B}}$ by $0.012-0.019 \AA(3 \sigma-5 \sigma)$. As expected, the shorter $\mathrm{C}-\mathrm{O}$ and $\mathrm{N}-\mathrm{O}$ bonds are adjacent to the longer $\mathrm{Zr}-\mathrm{O}$ bonds, and vice versa, thus preserving the quasi-twofold symmetry. Ligand bond distances and angles are in good agreement with the values found in other acetylacetonate ${ }^{25}$ and nitrate ${ }^{18}$ structures. As is always the case in structures which contain "symmetrically" bidentate nitrate groups, ${ }^{26}$ the terminal $\mathrm{N}-\mathrm{O}$ bonds ( $1.202 \AA$ ) are shorter and the $\mathrm{N}-\mathrm{O}$ bonds involving the coordinated oxygen atoms ( 1.267 and $1.282 \AA$ ) are longer than the $\mathrm{N}-\mathrm{O}$ bonds in the nitrate ion ( $1.245 \AA^{18}$ ); also the $\mathrm{O}-\mathrm{N}-\mathrm{O}$ bond angles involving the coordinated oxygen atoms (113.3 ${ }^{\circ}$ ) are appreciably less than $120^{\circ}$. The $\mathrm{NO}_{3}{ }^{-}$ligands are almost exactly planar (Table IX), while the seven atoms of each $\mathrm{C}_{5} \mathrm{O}_{2}$ acetylacetonate skeleton exhibit only minor departures from planarity; displacements from the $\mathrm{C}_{5} \mathrm{O}_{2}$ mean planes are $\leq 0.06 \AA$ (average displacement $0.022 \AA$ ). The Zr atom is slightly displaced from the mean plane of each ligand (Table IX). which implies that the chelate rings are slightly folded along the $m$ edges ( $\mathrm{O} \ldots \mathrm{O}$ ) of the dodecahedron. The dihedral angles between the ligand planes and the planes defined by the appropriate $\mathrm{O}-\mathrm{Zr}-\mathrm{O}$ group are $0.9,5.6,1.7$, and $4.5^{\circ}$ for rings $\mathrm{a}, \mathrm{b}, \mathrm{c}$, and d , respectively. The direction of the fold in all four rings is clockwise as viewed down the pseudo- $\overline{4}$ axis of Figure 2; i.e. the uncoordinated parts of ligand $a$ are folded toward ligand $b$, ligand $b$ is folded toward ligand c , etc.

Although hydrogen atoms have been located in several metal acetylacetonate structures, ${ }^{27}$ no attention seems to

$a X, Y$, and $Z$ are orthogonal coordinates measured in $\AA$ along $a$, $b$, and $c^{*}$, respectively, of the crystallographic coordinate system.
have been paid to the orientation of the methyl groups. In $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ one hydrogen atom of each of the four crystallographically independent methyl groups lies in (or near) the plane (Table IX) of the appropriate $\mathrm{C}_{5} \mathrm{O}_{2}$ group, and this hydrogen atom is eclipsed with $\mathrm{H}_{\mathrm{a}}$ or $\mathrm{H}_{\mathrm{b}}$, the hydrogen atom on the middle carbon atom (cf. Figures 2 and 4). This conformation is less favorable sterically than the staggered conformation accessible by a $60^{\circ}$ rotation about the $\mathrm{C}-\mathrm{CH}_{3}$ bond; however, the contacts between $\mathrm{H}_{\mathrm{a} 3}$ or $\mathrm{H}_{\mathrm{b} 3}$ and the nearest neighbor methyl hydrogen atoms (2.35$2.43 \AA$ ) are not excessively short compared with the van der Waals diameter of $2.4 \AA^{28}$ for hydrogen. ${ }^{29}$ These contacts may be attractive. The methyl groups adopt the same eclipsed conformation in $\operatorname{Pt}(\mathrm{acac})_{2} \mathrm{I}_{2} .{ }^{27 \mathrm{a}}$ However, the staggered conformation is found in Co (salen)(acac), ${ }^{27 \mathrm{~b}}$ and both staggered and eclipsed conformations are observed in $\mathrm{Sc}(\mathrm{acac})_{3 .}{ }^{27 \mathrm{c}}$ Thus, the optimum conformation is probably determined by the interplay of several competing factors, including both intra- and intermolecular van der Waals interactions.

Structure in Solution. $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ is a monomeric nonelectrolyte in nitrobenzene, and infrared spectra of dichloromethane solutions indicate that all carbonyl groups are coordinated to the metal. Moreover, similarity of solid state and solution infrared spectra make it seem unlikely that there is a change in the mode of nitrate coordination, with a consequent change in coordination number, on going from the solid state to solution; a detailed infrared and Raman study is in progress.

Proton NMR spectra of dichloromethane solutions at ambient temperature and $\mathrm{CHClF}_{2}$ solutions at temperatures as low as $-130^{\circ}$ indicate that $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ is stereochemically nonrigid on the NMR time scale. At lower temperatures, however, the single, time-averaged methyl resonance splits into two lines of equal intensity (coalescence temperature, $T_{\mathrm{c}}=-144^{\circ}$ ). ${ }^{30}$ The spectra at temperatures below $T_{\mathrm{c}}$ (two $-\mathrm{CH}_{3}$ resonances and one $-\mathrm{CH}=$ resonance) suggest that $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ exists in solution as a single stereoisomer having twofold symmetry. While these spectra do not define a unique structure, they are fully consistent with the $C_{2}-\mathrm{mmmm}$ dodecahedral structure found in the solid state.

(21) If the nitrate ligand is considered to occupy only one coordination site, ${ }^{18}$ the $C_{2 v}$ isomer may be regarded as a pseudo-octahedral trans isomer, and the dodecahedral $C_{2}$ isomer as a pseudo-actariedral cis isomer. In this sense the stereochemistry of $\mathrm{Zr}(\mathrm{acac})_{2}\left(\mathrm{NO}_{3}\right)_{2}$ is related to that of $\mathrm{Zr}(\mathrm{acac})_{2} \mathrm{Cl}_{2}$, which exists as the cis isomer in solution. ${ }^{8}$
(22) In calculating this contact, observed distances (Tables IV and $V$ ) were assumed ( Zr -O(acac) $=2.096 \AA, \mathrm{Zr}-\mathrm{O}\left(\mathrm{NO}_{3}{ }^{-}\right)=2.295 \AA, m$ edge (acac) $=2.64 \AA, m$ edge $\left(\mathrm{NO}_{3}{ }^{-}\right)=2.13 \AA$, a edge $(\mathrm{acac}-\mathrm{acac})=2.66$ $\AA$ ) and the length of the a edge connecting the two $\mathrm{NO}_{3}{ }^{-}$ligands was allowed to vary so as to equalize the lengths of the eight $g$ edges. If the a edge $\left(\mathrm{NO}_{3}{ }^{-}-\mathrm{NO}_{3}{ }^{-}\right)$is maintained at $2.66 \AA$, four of the $g$ edges are $2.46 \AA$ and the other four are 3.09 A .

(26) The division between symmetrically bidentate and unsymmetrically bidentate nitrate groups is, of course, arbitrary. Addison et al. ${ }^{18}$ consider a coordinated nitrate group to be symmetrically bidentate if the two M-O bonds differ by less than $0.2 \AA$, and unsymmetrically bidentate, if the two M-O bonds differ by 0.2-0.7 A. Thus, the nitrate groups In Zr (acac) $2\left(\mathrm{NO}_{3}\right)_{2}$ would ordinarily be considered to be symmetrically bidentate, desplte the small but real differences in the two $\mathrm{Zr}-\mathrm{O}$ and $\mathrm{N}-\mathrm{O}$ bond lengths.

# Reactivity Patterns of Chromocene, Molybdenocene, and Tungstenocene Reaction Systems. I. Carbonyl Complex Formation as a Probe of Coordinative Unsaturation ${ }^{1 a}$ 

Kit L. Tang Wong ${ }^{1 b}$ and Hans H. Brintzinger*Ic<br>Contribution from the Department of Chemistry. The University of Michigan. Ann Arbor, Michigan 48104, and Fachbereich Chemie, Universität Konstanz, D 7750 Konstanz, West Germany. Received November 5. 1974

#### Abstract

Carbon monoxide is found to form a monocarbonyl complex with chromocene. Whereas $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Mo}(\mathrm{CO})$ and $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{~W}(\mathrm{CO})$ are thermally stable compounds, we find that the formation of $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Cr}(\mathrm{CO})$ is reversible; the associated enthalpy and entropy changes are $\Delta H_{f}{ }^{\circ}=-18.8 \pm 0.5 \mathrm{kcal} / \mathrm{mol}$ and $\Delta S_{f}{ }^{\circ}=-60 \pm 2 \mathrm{eu}$. The dicarbonyl complexes $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{C}_{5} \mathrm{H}_{7}\right) \mathrm{M}(\mathrm{CO})_{2}$ are stable for all three group 6 metals, $\mathrm{M}=\mathrm{Cr}$, Mo, and W . Tungstenocene, on the other hand, is unique in forming a stable dicarbonyl complex $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{~W}(\mathrm{CO})_{2}$ which exceeds an 18 -valence-electron configuration. Factors contributing to the increasing accessibility of the metal center in the series $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Cr},\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Mo},\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{~W}$ to CO coordination are discussed and put in parallel to reactions of these species with other types of substrates.

Some time ago, we and others have reported on remarkable gradations in reactivity among the coordinatively unsaturated group 6 transition metal metallocenes. ${ }^{2-4}$ Chromocene appears to be a fairly nonreactive particle, whereas both molybdenocene and tungstenocene, generated as intermediates from a number of reaction systems, will undergo a variety of basic addition and insertion steps of potential interest for homogeneous catalysis. Of the three metallocenes, however, only tungstenocene is capable of inserting into the $\mathrm{C}-\mathrm{H}$ bond of aromatic hydrocarbons. In order to gain a more detailed understanding of factors contributing to this variation in reactivity, we have undertaken a systematic study of the reactions of carbon monoxide with this series of coordinatively unsaturated particles, as a particularly simple and efficient probe for coordinative unsaturation.

To date, monocarbonyl complexes have been described for molybdenocene and tungstenocene, ${ }^{3.4}$ but not for chromocene. A stable dicarbonyl complex of composition $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\mathrm{C}_{5} \mathrm{H}_{7}\right) \mathrm{Cr}(\mathrm{CO})_{2}$, on the other hand, has long been known to arise as one of the products when chromocene is exposed to both CO and $\mathrm{H}_{2} .{ }^{5}$ Preliminary reports on a related complex derived from molybdenocene have appeared in the literature recently. ${ }^{6}$ We wish to report here a more systematic characterization of these known species, as well as observations on the occurrence of novel carbonyl complexes for both chromocene and tungstenocene.

## Results and Discussion

1. Formation and Properties of $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Cr}(\mathrm{CO})$. When solutions of chromocene in petroleum ether or toluene are exposed to carbon monoxide, one observes a change in the visible spectrum. At CO pressures increasing from about

100 Torr to one atmosphere or more, one observes a diminution and final disappearance of the characteristic chromocene absorption at 454 nm . The reversibility of this reaction is established by the reappearance of this absorption band upon removal of the CO atmosphere. In a series of analogous experiments, we were unable to detect any interaction of chromocene with hydrogen gas, ethylene, 2 -butyne, or diphenylacetylene.

Since complex formation is far from stoichiometric at room temperature, we have further characterized the complex formed from chromocene and carbon monoxide at lower temperatures. One finds that a petroleum ether solution of chromocene takes up CO at $-78^{\circ}$ under formation of a brownish precipitate which is stable against loss of CO in vacuo at this temperature. When warmed to room temperature, this complex loses 1 mmol of CO per millimole of chromocene; this establishes the $1: 1$ composition of the carbonyl complex formed. A determination of the equilibrium constant for the reaction $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Cr}($ sol $)+\mathrm{CO}(\mathrm{gas}) \rightleftharpoons$ $\left(\mathrm{C}_{5} \mathrm{H}_{5}\right)_{2} \mathrm{Cr}(\mathrm{CO})$ (sol) (sol $=$ in toluene solution) is most conveniently performed by measuring the equilibrium pressure of CO (gas) over a partially carbonylated chromocene solution; measurements at different temperatures then yield the reaction enthalpy for this complex formation reaction. From the data presented in Table I we determine a standard enthalpy of complex formation of $-18.8 \pm 0.5 \mathrm{kcal} /$ mol and an associated entropy change of $-60 \pm 2 \mathrm{eu} .^{7}$

In the ${ }^{1} \mathrm{H}$ NMR spectrum of a toluene- $d_{8}$ solution of the carbonyl complex one sharp singlet is observed at $\tau 6.06$ ppm , consistent with chemical shifts obtained with comparable, diamagnetic $\mathrm{C}_{5} \mathrm{H}_{5}$ complexes. Above $0^{\circ}$ there is an increasing broadening of the singlet at $\tau 6.06$, due to the re-
