# Reaction of Thiol Anions with Benzene Oxide and Malachite Green 

D. M. E. Reuben ${ }^{1}$ and Thomas C. Bruice*<br>Contribution from the Department of Chemistry, University of California, Santa Barbara, Santa Barbara, California 93106. Received April 22, 1975

#### Abstract

The second-order rate constants for the reactions of a number of thiol anions with benzene oxide (BO) have been determined as have the rate constants and equilibria for the reaction of thiol anions with the acid-base equilibria species of malachite green (MG). $\beta$ constants for reaction of thiol anion and amines with the nonprotonated species of malachite green are comparable ( $\sim 0.3$ ) to the $\beta$ constants for the reactions of amines and thiol anions with ethylene oxide ( EO ) and thiol anions with BO. In addition the rate constants for the reaction of thiol anions with BO and EO are comparable. These results are discussed in terms of attack of $\mathrm{RS}^{-}$directly upon BO and EO in an SN 2 reaction vs. trapping of intimate ion pairs by $\mathrm{RS}^{-}$. As compared with the ability of ethylene oxide to react with nucleophiles possessing basicities as low as that of water, benzene oxide is attacked by only the more polarizable nucleophile as $\mathrm{N}_{3}{ }^{-}, \mathrm{RS}^{-}$, etc. This is shown to be due not to the greater selectivity of benzene oxide toward soft bases, but to the fact that the spontaneous aromatization rate (i.e., water rate) of benzene oxide exceeds the rate of reaction of ethylene oxide with water by ca. $10^{3}$. It is predicted that benzene oxides substituted with highly electron-withdrawing groups will exhibit reactivity to a broad range of nucleophiles. This prediction is predicated on the previously determined fact that aromatization of benzene oxide is associated with a $\rho \simeq-7$. For the purposes of this study, it was desirable to determine the microscopic $\mathrm{p} K_{\mathrm{a}}$ values for the thiol species under the conditions of the kinetic and thermodynamic studies ( $30^{\circ}$, solvent water, $\mu=1.0$ ). These constants are reported herein and compared with literature values.

As part of the normal metabolic paths of catabolism and detoxification, both biotic and exobiotic aromatic structures are converted to arene oxides. However, these normal metabolic processes may result in the assassination of the subject. Thus, arene oxide moieties formed from exobiotic aromatic hydrocarbons have been implicated as causative agents in mutagenesis, carcinogenesis, and tissue necrosis. ${ }^{2.3}$ The pathological effects of arene oxides have been attributed to their acting as alkylating agents. ${ }^{4-7}$ The enzyme ${ }^{8}$ and nonenzyme mediated 1,2 -addition of the sulfhydryl group of glutathione to arene oxides appears as a major

[^0]means of protection from the cytotoxic effects of these agents. Thus, both the cytotoxic effects of arene oxides and the detoxification of these substances involve nucleophilic addition to the oxide moiety. The importance of understanding the mechanisms of nucleophilic addition to arene oxides is obvious. Important studies dealing with the formation of products and their stereochemistry have been published ${ }^{9-16}$ but, with the possible exception of the hydration of 8,9 -indane oxide, ${ }^{16}$ no kinetic investigations of the nucleophilic addition to arene oxide have appeared. ${ }^{17}$ The present investigation deals with the kinetics of addition of thiol anions to benzene oxides. The magnitude of the rate constants and their sensitivity to the proton basicity of the

Figure 1. Plots of the concentration of total thiol vs. $k_{\text {obsd }}$ for the disappearance of benzene oxide from solution: (A) cysteine ethyl ester at pH values of $7.46,7.64,8.59,9.00$, and 9.17 ; (B) glutathione at pH values of $8.39,8.75,9.01$, and 9.17 ; (C) thioglycolate at $\mathrm{pH} 9.21,9.81$, and 10.44.
thiol anion is compared when the substrate is benzene oxide, ethylene oxide, and the delocalized carbonium ion of malachite green. For the present investigation and those that will follow, we desired a series of thiols whose varied microscopic $\mathrm{p} K_{\mathrm{a}}$ 's were known at a given temperature, at low total thiol concentration, and at a high constant ionic strength. The microscopic $\mathrm{p} K_{\mathrm{a}}$ values of seven thiols are reported at $30^{\circ}$, solvent $\mathrm{H}_{2} \mathrm{O}, \mu=0.1$.

## Experimental Section

Materials. Benzene oxide was prepared by literature procedures. ${ }^{18}$ The hydrochlorides of L-cysteine ethyl ester and $\beta$-mercaptoethylamine (Sigma) were recrystallized from ethanol-ether. 2-Mercaptoethanol (Sigma), sodium thioglycolate (Sigma), D,Lhomocysteine (National Biochemical), glutathione (National Biochemical), L-cysteine hydrochloride (Calbio-Chem) and malachite green (as oxalate from MCB) were employed without further purification. Doubly glass-distilled water was employed in all the various studies.

Microscopic $\mathbf{p} K_{\mathbf{2}}$ 's of Thiols at $30^{\circ}$. The $\mathrm{p} K_{\mathrm{a}}$ values of the thiols ( $5 \times 10^{-5} M$ ) were determined spectrally [ $30.0 \pm 0.1^{\circ} ; \mu=1.0$ $(\mathrm{KCl})$ in $\mathrm{H}_{2} \mathrm{O}$ ] employing a titration cell especially designed for the Cary 15 spectrophotometer. ${ }^{19}$ Trace heavy metal ion contaminants were removed from the aqueous KCl solvent by shaking with a $0.01 \%$ solution of dithiazone in $\mathrm{CCl}_{4}$. The aqueous layer was then extracted several times with $\mathrm{CCl}_{4}$ and remaining $\mathrm{CCl}_{4}$ removed by passing argon through the solution. All operations carried out for removal of trace metal ions and the handling of thiol solutions were performed in Nalgene plastic wear. The titration cell ${ }^{19}$ was constructed of polypropylene with quartz windows. The solution in the cell was magnetically stirred and pH monitored continuously using a Radiometer 26 pH meter and a EA 125 combined Metrohm microelectrode. An ABU 1 C Radiometer autoburet charged with 0.1 M KOH was employed for the titrations. All solutions were deoxygenated by bubbling argon through them for 1 hr . Argon was continuously passed through the titration cell. The argon itself was deoxygenated by passage through two vanadous ion traps.

Reaction of Thiols with Benzene Oxide. The disappearance of benzene oxide was followed at 320 nm by use of a Giiford Model 2000 spectrophotometer ( $30 \pm 0.1^{\circ}, \mu=1.0$ with KCl , solvent $\mathrm{H}_{2} \mathrm{O}$ ). In a typical experiment, a solution of mercaptan in 1 M KCl was brought to the desired pH with 1 M KOH and an aliquot taken and diluted with 1 M KCl to provide the desired concentration ( 0.02 to 0.1 M ). About 3 ml of the solution was then placed in a cuvette and allowed to temperature equilibrate for 15 min at which time the reaction was initiated by addition of $20 \lambda$ of a solution of benzene oxide in peroxide free dioxane to provide a solution ca. $10^{-4} \mathrm{M}$ in substrate. Reactions were carried out at five thiol concentrations at each of three pH values for those thiols possess-
ing no other ionizable groups in the pH range of interest. For thiols possessing other interferring ionizable groups, kinetic studies were carried out at each of five thiol concentrations at four or more different pH values (Figure 1). The observed pseudo-first-order rate constants were obtained using a linear least-squares program and a Hewlett Packard Model 9820A desk top computer.

Reaction of Thiols with Malachite Green (MG). These reactions were followed spectrophotometrically ( $30 \pm 1^{\circ}, \mu=1.0$ with KCl , solvent $\mathrm{H}_{2} \mathrm{O}$ ) by monitoring the decrease in absorbance at 618 nm , employing either a Cary 15 spectrophotometer equipped with an auto-titration and pH -stat cell 19 flushed with vanadous ion scrubbed argon or a Durrum stopped-flow spectrophotometer under nitrogen. Stock solutions of MG in $\mathrm{CH}_{3} \mathrm{CN}$ were prepared, and the concentration of MG was determined by addition of 0.5 ml of the stock solution to 25 ml of $\mathrm{H}_{2} \mathrm{O}$ and observing the absorbance at $618 \mathrm{~nm}\left(\epsilon_{1}=2.14 \times 10^{5} \mathrm{M}^{-1}\right.$ between pH 2.7 and 7.0 , length of Cary cell $\simeq 3.51 \mathrm{~cm}$ ). In a typical kinetic experiment, a $250-\mathrm{ml}$ solution of thiol was prepared. A $25-\mathrm{ml}$ aliquot was then pipetted into the polyethylene optical cell and the pH adjusted with either 1 $M \mathrm{KOH}$ or $1 M \mathrm{HCl}$. After temperature equilibration, the reaction was initiated by addition of 0.5 ml of the $\mathrm{CH}_{3} \mathrm{CN}$ solution of MG. In those instances for which stopped-flow measurements were required, either the thiol served as its own buffer or the thiol solution was buffered by 0.05 M acetate-acetic acid. A solution of thiol (twice the desired concentration) in 1.0 M KCl was brought to the desired pH and then placed in one of the stopped-flow syringes. The other syringe was filled with 1.0 M KCl solution containing twice the desired concentration of MG. The actual pH of the reaction solution was determined by mixing equal volumes of the MG and thiol solution outside the stopped-flow apparatus. In all cases the pH was within 0.02 pH units of that of the original thiol solution.

## Results

Thiol $\mathrm{p} K_{\mathrm{a}}$ Values. Although the $\mathrm{p} K_{\mathrm{a}}$ values for biologically important thiols have been determined by various investigators, we desired a set of $\mathrm{p} K_{\mathrm{a}}$ 's determined in water at a single temperature $\left(30^{\circ}\right)$. For a discussion of operational methodology and a derivation of the necessary equations, one should consult the now classic study of Benesch and Benesch. ${ }^{20}$ In the absence of substituent groups whose $\mathrm{p} K_{\mathrm{a}}$ values lie in the range of the $\mathrm{p} K_{\mathrm{a}}$ of the thiol function, $K_{\text {RSH }}$ is provided by eq 1

$$
\begin{equation*}
K_{\mathrm{RSH}}=a_{\mathrm{H}}(\mathrm{OD})_{\mathrm{n}} /\left[(\mathrm{OD})_{\mathrm{f}}-(\mathrm{OD})_{\mathrm{n}}\right] \tag{1}
\end{equation*}
$$

where $K_{\text {RSH }}=$ acid dissociation constant of RSH, $a_{\mathrm{H}}=$ hydrogen ion activity as determined by the glass electrode, $(O D)_{\mathrm{f}}=$ optical density of $\mathrm{RS}^{-}$obtained at high pH , and $(\mathrm{OD})_{\mathrm{n}}=\mathrm{OD}$ at measured pH . Values of $K_{\mathrm{RSH}}$ were obtained by computer iteration which generated sigmoid plots of percent $\left[\mathrm{RS}^{-}\right]$vs. pH . In all cases, the individual paints (10-20) precisely fitted the titration curves (not shown). In those instances where an ionizable $-\mathrm{NH}_{3}{ }^{+}$function was present, the microscopic $K_{\mathrm{a}}$ values (eq 2) were obtained by

assuming, after Benesch and Benesch, ${ }^{20}$ that $\epsilon$ of the $-S^{-}$ $(\sim 240 \mathrm{~nm})$ function remains invariant to the state of ionization of the $-\mathrm{NH}_{3}+$ function (eq 3 ).

Figure 2. Fit of experimental points of eq 3 for the determination of the microscopic $\mathrm{p} K_{\mathrm{a}}$ value of the thiol functions of cysteine ethyl ester, cysteine, and D.L-homocysteine. For glutathione, the experimental points are fitted to an equation for a single sulfhydryl $\mathrm{p} K_{\mathrm{a}}$ (eq 1).

$$
\begin{equation*}
\frac{\left[\mathrm{RS}^{-}\right]}{\left[\mathrm{RS}^{-}\right]_{\max }}=\frac{K_{\mathrm{a}} / K_{\mathrm{b}}+K_{\mathrm{d}} / a_{\mathrm{H}}}{a_{\mathrm{H}} / K_{\mathrm{b}}+K_{\mathrm{a}} / K_{\mathrm{b}}+K_{\mathrm{d}} / a_{\mathrm{H}}+1} \tag{3}
\end{equation*}
$$

Equation 3 contains the three unknown quantities $K_{\mathrm{a}}, K_{\mathrm{b}}$, and $K_{\mathrm{d}}$ and requires three values of $\left[\mathrm{RS}^{-}\right] /\left[\mathrm{RS}^{-}\right]_{\text {max }}$ at three pH 's for solution. In practice, 25 values of [RS ${ }^{-}$]/ [ $\left.\mathrm{RS}^{-}\right]_{\text {max }}$ at 25 pH values were determined and a computer program employed which calculated the dissociation constants employing three points at a time, each point being from a different portion of the titration curve. An average value of each of the constants so determined was employed to generate the theoretical curves to fit the experimental points (Figure 2). Examination of Figure 2 reveals that both glutathione and D,L-homocysteine show no break in their thiol titration curves. The glutathione data fit best a single ionization, and attempts to calculate microscopic $\mathrm{p} K_{\mathrm{a}}$ values result in identical values for $K_{\mathrm{a}}$ and $K_{\mathrm{d}}$ (insensitivity to the amino group $\mathrm{p} K_{\mathrm{a}}$ ). On the other hand, the D,L-homocysteine data could only be fit employing eq 3 . The assumption of a single thiol ionization constant provided a poor fit to the experimental points. In order to determine the $\mathrm{p} K_{\mathrm{a}}$ of the amino group of glutathione, the following procedure was employed. The value of $\left[\mathrm{RS}^{-}\right]$was determined at each pH employing the determined thiol ionization constant and the concentration of neutral amine species $\left[\mathrm{RNH}_{2}\right]$ obtained from eq 4.

$$
\begin{align*}
& {\left[\mathrm{RNH}_{2}\right]=\frac{\text { moles of base added }}{\text { volume }}-} \\
& \quad\left[\mathrm{RS}^{-}\right]-\left(\left[\mathrm{HO}^{-}\right]-\left[\mathrm{HO}^{-}\right]_{\text {initiai }}\right) \tag{4}
\end{align*}
$$

The generated values of $\left[\mathrm{RNH}_{2}\right]$ were then employed to calculate the amine $\mathrm{p} K_{\mathrm{a}}$. The $\mathrm{p} K_{\mathrm{a}}$ values determined in this study are provided in Table I. Assignment of the $\mathrm{p} K_{\mathrm{a}}$ values to discrete species is provided in Table II.

Reaction of Thiols with Benzene Oxide (BO). All kinetic experiments were carried out at constant pH values and in the presence of total thiol $\left([\mathrm{RSH}]_{\mathrm{T}}=\left[\mathrm{RS}^{-}\right]+[\mathrm{RSH}]\right)$ greatly exceeding [BO]. Under these conditions, first-order kinetics prevail (Figure 1). In initial experiments, it was determined that undissociated thiol exhibits no measureable rate of reaction with BO. It has previously been shown that benzene oxide is converted to phenol via specific acid catalyzed and spontaneous pathways. ${ }^{27}$ In the alkaline pH range employed in these studies, only the spontaneous ( $k_{0}$ ) aromatization of BO is evident. Thus, for thiols possessing a

${ }^{a}$ This study, ${ }^{b}$ Benesch and Benesch, ref 20. $c$ Elson and Edsall, ref 21. $d$ Danehy and Noel, ref 22. e Rabenstein, ref 23.
single sulfhydryl ionization constant ( $\beta$-mercaptoethylamine, 2-mercaptoethanol, and thioglycolic acid), the pseudo-first-order rate constant ( $k_{\text {obsd }}$ ) is provided by eq 5.

$$
\begin{align*}
& -\frac{\mathrm{d}[\mathrm{BO}]}{\mathrm{d} t}=k_{\mathrm{obsd}}[\mathrm{BO}] \\
& k_{\mathrm{obsd}}=k_{0}+k_{2}\left[\mathrm{RS}^{-}\right]  \tag{5}\\
& =k_{0}+\frac{k_{2} K_{\mathrm{a}}[\mathrm{RSH}]_{\mathrm{T}}}{K_{\mathrm{a}}+a_{\mathrm{H}}}
\end{align*}
$$

From eq 5 plots of $k_{\text {obsd }}$ at constant pH vs. [RSH] $]_{\text {provide }}$ as slope $k_{2} K_{\mathrm{a}} /\left(K_{\mathrm{a}}+a_{\mathrm{H}}\right)$ and as intercept $k_{0}$. Multiplication of the slopes by $K_{\mathrm{a}} /\left(K_{\mathrm{a}}+a_{\mathrm{H}}\right)$ provides the value of $k_{2}$ at each pH . The average values of $k_{2}$, so obtained, are included in Table II. For cysteine, cysteine ethyl ester, and D,L-homocysteine, the rate constants for each thiol anion species were determined separately. For these cases the rate law of eq 6 prevails.

$$
\begin{align*}
k_{\text {obsd }} & =k_{0}+k_{\mathrm{HA}}\left[\mathrm{~S}^{-} \mathrm{NH}_{3}{ }^{+}\right]+k_{\mathrm{A}}\left[\mathrm{~S}^{-} \mathrm{NH}_{2}\right] \\
& =k_{0}+\left[\mathrm{S}^{-} \mathrm{NH}_{3}{ }^{+}\right]\left\{\frac{k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{c}}}{a_{\mathrm{H}}}\right\} \tag{6}
\end{align*}
$$

Material balance in $[\mathrm{RSH}]_{\mathrm{T}}$ (eq 7)

$$
\begin{align*}
& {[\mathrm{RSH}]_{\mathrm{T}}=} \frac{a_{\mathrm{H}}\left[\mathrm{~S}^{-} \mathrm{NH}_{3}^{+}\right]}{K_{\mathrm{a}}}+\left[\mathrm{S}^{-} \mathrm{NH}_{3}^{+}\right]+ \\
& \frac{K_{\mathrm{b}}}{K_{\mathrm{a}}}\left[\mathrm{~S}^{-} \mathrm{NH}_{3}^{+}\right]+\frac{K_{\mathrm{c}}\left[\mathrm{~S}^{-} \mathrm{NH}_{3}^{+}\right]}{a_{\mathrm{H}}} \tag{7}
\end{align*}
$$

provides eq 8

$$
\begin{equation*}
\left[\mathrm{S}^{-} \mathrm{NH}_{3}^{+}\right]=[\mathrm{RSH}]_{\mathrm{T}}\left\{\frac{K_{\mathrm{a}} a_{\mathrm{H}}}{K_{\mathrm{a}} K_{\mathrm{c}}+\left(K_{\mathrm{a}}+K_{\mathrm{b}}\right) a_{\mathrm{H}}+a_{\mathrm{H}}^{2}}\right\} \tag{8}
\end{equation*}
$$

and substitution of eq 8 into eq 6 yields eq 9 .

$$
\begin{align*}
k_{\mathrm{obsd}}= & k_{0}+[\mathrm{RSH}]_{\mathrm{T}}\left\{\frac{K_{\mathrm{a}}\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{c}}\right)}{K_{\mathrm{a}} K_{\mathrm{c}}+\left(K_{\mathrm{a}}+K_{\mathrm{b}}\right) a_{\mathrm{H}}+a_{\mathrm{H}^{2}}}\right\} \\
& =k_{0}+[\mathrm{RSH}]_{\mathrm{T}} Q\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{c}}\right) \tag{9}
\end{align*}
$$

Values of $k_{\mathrm{HA}}$ and $k_{\mathrm{A}}$ were obtained by plotting $k_{\text {obsd }}$ vs. [RSH] ${ }_{T}$ at constant values of pH and obtaining as slope $Q\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{c}}\right)$ and intercept as $k_{0}$. In a secondary plot, the slopes divided by $Q$ were plotted vs. $a_{\mathrm{H}}$ to provide $k_{\mathrm{HA}}$ as slope ${ }^{\prime}$ and $k_{\mathrm{A}} K_{\mathrm{c}}$ as intercept ${ }^{\prime}$.

For glutathione we have determined that the $\mathrm{p} K_{\mathrm{a}}$ of the thiol function is not affected by the ionization state of the
amino group. However, it is possible that the nucleophilicity of the $\mathrm{S}^{-} \mathrm{NH}_{3}{ }^{+}$and $\mathrm{S}^{-} \mathrm{NH}_{2}$ species could be different (eq 10 ). From a material balance, eq 10 is equivalent to eq 11.

$$
\begin{align*}
k_{\text {obsd }} & =k_{0}+k_{\mathrm{HA}}\left[\mathrm{~S}-\mathrm{NH}_{3}+\right]+k_{\mathrm{A}}\left[\mathrm{~S}^{-} \mathrm{NH}_{2}\right]  \tag{10}\\
k_{\text {obsd }} & =k_{0}+[\mathrm{RSH}]_{\mathrm{T}}\left\{\frac{\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{a}_{2}}\right) K_{\mathrm{a}_{1}}}{K_{\mathrm{a}_{1}} K_{\mathrm{a}_{2}}+K_{\mathrm{a} 1} a_{\mathrm{H}}+a_{\mathrm{H}^{2}}}\right\} \\
& =k_{0}+[\mathrm{RSH}]_{\mathrm{T}} R\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{a}_{2}}\right) \tag{11}
\end{align*}
$$

Plots of $k_{\text {obsd }}$ at constant pH vs. [RSH] $]_{\mathrm{T}}$ provide $R\left(k_{\mathrm{HA}} a_{\mathrm{H}}\right.$ $+k_{\mathrm{A}} K_{\mathrm{a}_{2}}$ ) as slope and $k_{0}$ as intercept. In a secondary plot of slope $/ R$ vs. $a_{\mathrm{H}}$, there was obtained $k_{\mathrm{HA}}$ as slope ${ }^{\prime}$ and $k_{\mathrm{A}} K_{\mathrm{a} 2}$ as intercept ${ }^{\prime}$.

Reaction of Thiols with Malachite Green (MG). These reactions were carried out under the pseudo-first-order conditions of $[\mathrm{RSH}]_{\mathrm{T}} \gg[\mathrm{MG}]$. In addition to the thiol species $\mathrm{NH}_{3}{ }^{+} \mathrm{SH}, \quad \mathrm{NH}_{2} \mathrm{SH}, \quad \mathrm{NH}_{3}{ }^{+} \mathrm{S}^{-}$and $\mathrm{NH}_{2} \mathrm{~S}^{-}$, the species $\mathrm{H}_{2} \mathrm{~A}^{3+}, \mathrm{HA}^{2+}, \mathrm{A}^{+}, \mathrm{H}_{2} \mathrm{ASR}^{2+}, \mathrm{HASR}^{+}$, and ASR must be considered:

In the structures $\mathrm{H}_{2} \mathrm{ASR}^{2+}$, $\mathrm{HASR}^{+}$, and ASR, the symbol $R$ refers to the remainder of the thiol nucleophile structure associated with the particular microscopic $\mathrm{p} K$ (Table II). The sequence of Scheme I accounts for the equilibrium re-

${ }^{a}$ lonization of the $\alpha$-amino group ( $\mathrm{p} K_{\mathrm{a}}=9.46$ ) provides a moderate increase in rate constant.
sults of this study. Spectral titration of MG below pH 2.5 is accompanied by a decrease in absorbance at 618 nm and an increase in absorbance at 446 nm which is associated with the prototropic equilibria between the MG species $\mathrm{H}_{2} \mathrm{~A}^{3+}$ and $\mathrm{HA}^{2+}\left(\mathrm{p} K_{\mathrm{a}_{1}}<1.0\right)$. All equilibrium measurements were restricted to pH values of 2.8 or greater. For this reason it was not essential to take into account the species $\mathrm{H}_{2} \mathrm{~A}^{3+}$ in our calculations.

Defining the equilibrium constant $K_{\text {obsd }}$ as in eq 12

$$
\begin{equation*}
K_{\mathrm{obsd}}=\frac{\left[\mathrm{H}_{2} \mathrm{ASR}^{2+}\right]+\left[\mathrm{HASR}^{+}\right]+[\mathrm{ASR}]}{\left[\mathrm{HA}^{2+}+\mathrm{A}^{+}\right][\mathrm{RSH}]_{\mathrm{T}}} \tag{12}
\end{equation*}
$$

and employing the equilibrium expression of Scheme I, one obtains eq 13

$$
\begin{equation*}
K_{\mathrm{obsd}}=\frac{\left[\mathrm{H}_{2} \mathrm{ASR}^{2+}\right]\left\{\frac{K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+K_{\mathrm{a}_{3}} a_{\mathrm{H}}+a_{\mathrm{H}^{2}}}{a_{\mathrm{H}^{2}}}\right\}}{\left\{\frac{\left[\mathrm{HA}^{2+}\right]\left(K_{\mathrm{a}_{2}}+a_{\mathrm{H}}\right)}{a_{\mathrm{H}}}\right\} \frac{\left[\mathrm{RS}^{-}\right]}{U}} \tag{13}
\end{equation*}
$$

where $U$ represents $K_{\mathrm{s}} /\left(K_{\mathrm{s}}+a_{\mathrm{H}}\right)$ for thioglycolic acid and cystamine and $K_{\mathrm{a}} a_{\mathrm{H}} /\left[K_{\mathrm{a}} K_{\mathrm{c}}+a_{\mathrm{H}}\left(K_{\mathrm{a}}+K_{\mathrm{b}}\right)+a_{\mathrm{H}^{2}}{ }^{2}\right]$ for cysteine and cysteine ethyl ester. The employment of $U=$ $K_{\mathrm{a}} a_{\mathrm{H}} /\left[K_{\mathrm{a}} K_{\mathrm{c}}+a_{\mathrm{H}}\left(K_{\mathrm{a}}+K_{\mathrm{b}}\right)+a_{\mathrm{H}^{2}}{ }^{2}\right.$ was predicated on the fact that, in the pH range employed, the concentration of $\mathrm{S}^{-} \mathrm{NH}_{2}$ is small compared with that of $\mathrm{S}^{-} \mathrm{NH}_{3}{ }^{+}$. Rearrangement of eq 13 provided eq 14.

$$
\begin{align*}
& \frac{K_{\text {ubsd }}}{U}\left(K_{\mathrm{a}_{2}}+a_{\mathrm{H}}\right)= \\
& \qquad \begin{array}{l}
{\left[\mathrm{H}_{2} \mathrm{ASR}^{2+}\right]\left(K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+K_{\mathrm{a}_{3}} a_{\mathrm{H}}+a_{\mathrm{H}}{ }^{2}\right)} \\
{\left[\mathrm{HA}^{2+}\right]\left[\mathrm{RS}^{-}\right] a_{\mathrm{H}}}
\end{array}  \tag{14}\\
& K_{12}=\frac{\left[\mathrm{H}_{2} \mathrm{ASR}^{2+}\right]}{\left[\mathrm{HA}^{2+}\right]\left[\mathrm{RS}^{-}\right] a_{\mathrm{H}}}
\end{align*}
$$

Substituting the equilibrium expression of eq 15 into eq 14 provides eq 16.

$$
\begin{gather*}
\frac{K_{\text {obsd }}}{U}\left\{\frac{\left(K_{\mathrm{a}_{2}}+a_{\mathrm{H}}\right)}{a_{\mathrm{H}}}\right\}-\frac{K_{12} K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}}{a_{\mathrm{H}}} \\
=K_{12}\left(K_{\mathrm{a} 3}+a_{\mathrm{H}}\right) \tag{16}
\end{gather*}
$$

Equation 16 may also be expressed in the form of eq 17.

$$
\begin{equation*}
K_{\mathrm{obsd}}=\frac{U K_{12}\left(K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+K_{\mathrm{a}_{3}} a_{\mathrm{H}}+a_{\mathrm{H}}^{2}\right)}{\left(K_{\mathrm{a} 2}+a_{\mathrm{H}}\right)} \tag{17}
\end{equation*}
$$

The solution of the various constants from experimental

${ }^{a}$ From intercept of plots of eq 24 at low $\mathrm{pH} .{ }^{b}$ From stopped-flow kinetics at high pH .

Figure 3. Log $K_{\text {obsd }}$ vs. pH profile for reaction of thiol anion species with malachite green. Points are experimental, and the line has been generated from eq 17 employing the constants of Table III.
data was carried out by two different procedures which provided consistent results. At low pH the first term of the left hand side of eq 16 is much larger than the second term. Thus, by plotting $K_{\text {obsd }}\left(K_{\mathrm{a} 2}+a_{\mathrm{H}}\right) / U a_{\mathrm{H}}$ vs. $a_{\mathrm{H}}$, a straight line should be obtained with slope $K_{12}$ and intercept $K_{\mathrm{a}_{3}} K_{12}$ with the points at higher pH deviating upward from the linear plot. A computer program was written for the purpose of iteration in the value of $K_{\mathrm{a}_{2}}$ to provide the best straight line for the first approximation of $K_{12}$. The best fit was taken as that with the greatest correlation coefficient (i.e., 0.99 plus). This method was found to be very sensitive to the chosen values of $K_{\mathrm{a}_{2}}$, with the line curving upward when the value for $K_{\mathrm{a}_{2}}$ is too high and downward when it is too low. The values of $K_{\mathrm{a}_{2}}$ and $K_{12}$ so obtained were then substituted into eq 16 and the left hand side of the equation was plotted vs. $a_{\mathrm{H}}$ and the product $K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}$ varied until the best fit to the theoretical line was obtained. The values of $K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}$ were then used to recalculate $K_{\mathrm{a}_{2}}$ and so on until the best set of consistent constants were obtained. The second approach was simply to employ eq 17 and chose the best constants as those which fitted $\log K_{\text {obsd }}$ values to a plot of $\log K_{\text {obsd }}$ vs. pH. For this purpose, an iteration procedure in $K_{12}, K_{\mathrm{a} 3}$, and $K_{\mathrm{a} 4}$ was employed along with the separately determined value of $K_{\mathrm{a}_{2}}$. The constants obtained from the two procedures were in close agreement. The determined equilibrium constants are given in Table III and plots of log $K_{\text {obsd }}$ vs. pH are provided in Figure 3.

The kinetics of the reaction of the thiolate anion species with MG were followed to equilibrium; thus, $k_{\text {obsd }}$ is the sum of forward $\left(k_{1}\right)$ and reverse ( $k_{-1}$ ) rate constants. From

Scheme II

thiol adducts

## Scheme III

eq 18 and 19 follow eq 20 and 21

$$
\begin{gather*}
k_{\mathrm{obsd}}=k_{1}+k_{-1}  \tag{18}\\
K^{\prime}=K_{\mathrm{obsd}}[\mathrm{RSH}]_{\mathrm{T}}=\frac{k_{1}}{k_{-1}}  \tag{19}\\
k_{1}=k_{\mathrm{obsd}}\left(\frac{K_{\mathrm{obsd}}[\mathrm{RSH}]_{\mathrm{T}}}{1+K_{\mathrm{obsd}}[\mathrm{RSH}]_{\mathrm{T}}}\right)  \tag{20}\\
k_{-1}=k_{\mathrm{obsd}} /\left(K_{\mathrm{obsd}}[\mathrm{RSH}]_{\mathrm{T}}+1\right) \tag{21}
\end{gather*}
$$

from which $k_{1}$ and $k_{-1}$ may be determined at each pH and concentration of $[\mathrm{RSH}]_{\mathrm{r}}$. By definition $k_{1}$ is the pH and $[\mathrm{RSH}]_{T}$ sensitive forward rate constant (eq 22) which is provided by eq 23 (Scheme II). Rearrangement of eq 23 provides 24 .

$$
\begin{gather*}
\nu_{\mathrm{f}}=k_{\mathrm{i}}[\mathrm{MG}]_{\mathrm{T}}  \tag{22}\\
k_{1}=\frac{\left(k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{a}_{2}}\right) U[\mathrm{RSH}]_{\mathrm{T}}}{\left(K_{\mathrm{a}_{2}}+a_{\mathrm{H}}\right)}  \tag{23}\\
\frac{k_{1}\left(K_{\mathrm{a} 2}+a_{\mathrm{H}}\right)}{U[\mathrm{RSH}]_{\mathrm{T}}}=k_{\mathrm{HA}} a_{\mathrm{H}}+k_{\mathrm{A}} K_{\mathrm{a} 2} \tag{24}
\end{gather*}
$$

From eq 24 a plot of the left hand term vs. $a_{\mathrm{H}}$ provides a straight line of slope $k_{\mathrm{HA}}$ and intercept $k_{\mathrm{A}} K_{\mathrm{a}_{2}}$. In Figure 4 are plotted the values of $\log k_{1}$ vs. pH . The curves have been generated from eq 23 employing the values of $k_{\mathrm{A}}$ and $k_{\mathrm{HA}}$ listed in Table III. The constant $k_{-1}$ pertains to the three paths of reversion of $\mathrm{H}_{2} \mathrm{ASR}^{2+}, \mathrm{HASR}^{+}$, and ASR to thiol and MG (Scheme III, eq 25, 26, and 27).

$$
\begin{gather*}
\nu_{\mathrm{r}}=k_{-1}[\mathrm{ASR}]_{\mathrm{T}}  \tag{25}\\
\nu_{\mathrm{r}}=\left(k_{\mathrm{H}_{2} \mathrm{~B}}\left[\mathrm{H}_{2} \mathrm{ASR}^{2+}\right]+k_{\mathrm{HB}}\left[\mathrm{HASR}^{+}\right]+k_{\mathrm{B}}[\mathrm{ASR}]\right)  \tag{26}\\
k_{-1}=\frac{k_{\mathrm{B}} K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+k_{\mathrm{HB} a_{\mathrm{H}} K_{\mathrm{a}_{3}}+k_{\mathrm{H}_{2} \mathrm{~B}} a_{\mathrm{H}^{2}}^{2}}^{K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+K_{\mathrm{a}_{3}} a_{\mathrm{H}}+a_{\mathrm{H}^{2}}}}{} \tag{27}
\end{gather*}
$$

Solution of eq 27 in terms of the various constants was approached through its fitting to a plot of $\log k_{-1}$ vs. pH . The results of these fittings revealed that the term $k_{\mathrm{H}_{2} \mathrm{~B}}$ must be quite small so that $k_{\mathrm{H}_{2} \mathrm{~B}} a_{\mathrm{H}}{ }^{2}$ in the numerator of eq 27 can be ignored. This allows the writing of eq 28.

$$
\begin{equation*}
k_{\mathrm{HB}} a_{\mathrm{H}}+k_{\mathrm{B}} K_{\mathrm{a}_{4}}=k_{-1} \frac{\left(K_{\mathrm{a}_{3}} K_{\mathrm{a}_{4}}+K_{\mathrm{a}_{3}} a_{\mathrm{H}}+a_{\mathrm{H}^{2}}\right)}{K_{\mathrm{a}_{3}}} \tag{28}
\end{equation*}
$$

A plot of the right hand side of eq 28 vs. $a_{\mathrm{H}}$ provides a straight line of slope $k_{\mathrm{HB}}$ and intercept $k_{\mathrm{B}} K_{\mathrm{a} 4}$ when the correct values of $K_{\mathrm{a}_{3}}$ and $K_{\mathrm{a}_{4}}$ are employed.

## Discussion

Thiol $\mathrm{p} K_{\mathrm{a}}$ Values. The $\mathrm{p} K_{\mathrm{a}}$ values of the thiols of this study have been determined previously under varying experimental conditions. The measurements of this study were made at $30 \pm 0.1^{\circ}$ and at $\mu=1.0$ with thiol concentrations of $10^{-4}$ to $10^{-5} \mathrm{M}$. The Raman spectral determinations of Elson and Edsall ${ }^{21}$ were at ca. $25^{\circ}$ and employed thiol concentrations of 1 or 2 M . Measurements of thiol $\mathrm{p} K_{\mathrm{a}}$ values by Danehy and Noel ${ }^{22}$ were carried out at $30^{\circ}$ with thiol concentrations of about 0.01 M without added salt. The nuclear magnetic resonance measurements of Rabenstein ${ }^{23}$ were carried out at $25^{\circ}$ with $\mu$ varying from 0.2 to 0.53 and total thiol at 0.15 M . The spectral titrimetric measurements of Benesch and Benesch ${ }^{20}$ were carried out at $23^{\circ}, \mu=\mathrm{ca}$. 0.2 and total thiol of $10^{-4}$ to $10^{-5} \mathrm{M}$. Comparison of the microscopic $\mathrm{p} K_{\mathrm{a}}$ values obtained by us with those previously determined are provided in Table I. Examination of Table I reveals that: (1) for L-cysteine ethyl ester, our values are about 0.1 unit less than those determined by Benesch and Benesch; ${ }^{20}$ (2) for L-cysteine and cystamine, our values are 0.32 and 0.1 unit, respectively, less than those determined by Benesch and Benesch ${ }^{20}$ and by Elson and Edsall; ${ }^{21}$ (3) for glutathione, we find the ionization of the sulfhydryl group to be independent of the ionization of the ammonium group. Attempts to obtain microscopic $\mathrm{p} K_{\mathrm{a}}$ values resulted in $\mathrm{p} K_{\mathrm{a}}=\mathrm{p} K_{\mathrm{d}}$ and $\mathrm{p} K_{\mathrm{b}}=\mathrm{p} K_{\mathrm{c}}$ (eq 2). Rabenstein, ${ }^{23}$ on the other hand, was able to obtain microscopic $\mathrm{p} K_{\mathrm{a}}$ values for glutathione. The discrepancy may be due to the high concentration of glutathione employed in Rabenstein's study. The discrepancies between our titration data and those reported previously may be understood in part from the fact that the conditions of thiol concentration, temperature, and ionic strength are not duplicated from study to study.

Equilibrium Constants Determined from the Reactions of Thiols with Malachite Green. Both equilibrium and kinetic methods have been employed to determine the $\mathrm{p} K_{\mathrm{a}_{2}}, \mathrm{p} K_{\mathrm{a}_{3}}$, and $\mathrm{p} K_{\mathrm{a} 4}$ values of Scheme I (Table III). The method of equilibrium determination is sensitive to the assigned $\mathrm{p} K_{\mathrm{a}}$ values which should be accurate to $\pm 0.1$ or $\pm 0.2$ unit. Some discrepancy exists in the $\mathrm{p} K_{\text {app }}$ values determined by the two methods employed. This is not completely surprising for it is a general occurrence for $\mathrm{p} K_{\text {app }}$ values obtained via kinetic methods to differ by up to 0.5 or so log unit from the identical constant determined by a thermodynamic technique. ${ }^{24}$

Examination of Table III shows that there is a good agreement in the $\mathrm{p} K_{\mathrm{a}}$ values obtained from the reactions of cysteine, cysteine ethyl ester, and cystamine but that the values obtained with thioglycolic acid are significantly different. Considering the equilibrium constants obtained with cysteine, cysteine ethyl ester, and cystamine, the values of $\mathrm{p} K_{\mathrm{a}_{2}}(1.5 \pm 0.1), \mathrm{p} K_{\mathrm{a}_{3}}(4.3 \pm 0.1)$, and $\mathrm{p} K_{\mathrm{a}_{4}}(5.2 \pm 0.1)$ are in good agreement with those obtained by $\mathrm{Cigen}^{25}$ (1.45, 4.6, and 5.2 , respectively). In the present study, RS species provides the ligand to the carbonium ion while, in Cigen's studies, $\mathrm{HO}^{-}$was the ligand. The rather different

Figure 4. Upper portion: $\log k_{1}$ vs. pH for reaction of three thiols with MG. Points are experimental and the curve generated from eq 23 employing the values of $k_{1 A^{+}}$and $k_{1 \mathrm{HA}^{2}+}$ of Table 111. Lower portion: Log $k_{-1}$ vs. pH for dissociation of MG thiol adducts. Points are experimental and the curves generated from eq 28 employing the $k_{- \text {HASR }^{+}}$ and $k_{- \text {IASR }^{+}}$constants of Table III.
$\mathrm{p} K_{\mathrm{a}}$ values obtained when thioglycolate dianion serves as the $\mathrm{RS}^{-}$ligand require explanation. None appears more profound than the simple noting that thioglycolate possesses no charged ammonium substituent while MG, cysteine, cysteine ethyl ester, and cystamine do. It is possible that the thioglycolate dianion can complex with MG. Spectral and kinetic evidence for the ion pairing of MG with aryl sulfonates in aqueous solution have been obtained by Bunton and Paik. ${ }^{26}$ Charge repulsion between MG and the charged ammonium group on other thiol anion species could decrease any tendency toward complex formation. In any event, the rate constant $k_{\mathrm{HA}^{2+}}{ }^{2+}$ for thioglycolate may not be used in any linear free energy treatment in which it is compared with rate constants for the other thiols.

Rates of Reaction of Thiol Anions with Benzene Oxide and Malachite Green. Benzene and other simple arene oxides have been reported not to yield nucleophilic addition products on treatment with nonpolarizable nucleophiles as $\mathrm{NH}_{3}, \mathrm{NH}_{2}{ }^{-}$, and hydroxide ion. ${ }^{13}$ However, nucleophilic addition by hard or nonpolarizable nucleophiles does, albeit grudgingly, apparently occur when the reactions have been carried out in a solvent of low dielectric constant. In a typical experiment, a reaction period of 14 days is required to obtain a $64 \%$ yield of trans-6-methoxycyclohexa-2,4-diene1 -ol on reaction of BO with 4 equiv of $\mathrm{MeO}^{-}$in $\mathrm{MeOH} .{ }^{14}$ The ability of $\mathrm{MeO}^{-}$to react with the oxide in alcohol may be due to repression of the competing aromatization reaction through destabilization of the intermediate carbocation (vide infra) with a resultant increase in the $\Delta F^{\ddagger}$ for its formation. This speculation receives some support from the observation that both the spontaneous and acid catalyzed aromatization of benzene oxide, naphthalene oxide, and phenanthrene oxide are markedly depressed on decreasing the dielectric of the media. ${ }^{27}$ In contrast to the situation with nonpolarizable nucleophiles, attack by soft and polarizable nucleophiles as $\mathrm{RS}^{-}$and $\mathrm{N}_{3}{ }^{-}$is readily established. Thiophenoxide has been shown to provide with BO trans-6-phenylthiocyclohexa-2,4-dienol $\left(\mathrm{H}_{2} \mathrm{O}\right.$ solvent, $0^{\circ}$. 64\% yield). Further, by use of selectively deuterated BO, the reaction was established to occur solely via 1,2-addition (in

## Scheme IV

contrast to the trans-1,2 and trans-1,6 addition of $\mathrm{N}_{3}{ }^{-}$). Similar trans-1,2 addition of other thiol anions has been tacitly assumed. ${ }^{14}$

The most characteristic reactions of benzene oxides, naphthalene oxides, and non-K-region oxides of phenanthrene are specific acid and spontaneous epoxide ring opening to yield a carbonium ion which then rearranges to yield phenols (Scheme IV). Much evidence is available to support Scheme IV and rate-determining carbonium ion formation. This includes: (1) $\log k_{\text {obsd }}$ vs. pH rate profiles that establish two pathways, one first order in $\mathrm{H}_{3} \mathrm{O}^{+}$and the other spontaneous; ${ }^{27}$ (2) the marked decrease in rate accompanying substitution (benzene oxide) of electron-withdrawing groups ( $\rho \simeq-7$ ) for both specific acid and spontaneous paths; ${ }^{28}$ (3) lack of primary hydrogen/deuterium kinetic isotope effects for the NIH shift; ${ }^{28}$ (4) the establishment of oxygen migration (the so-called oxygen-walk); ${ }^{29}$ and (5) solvent trapping of intermediate carbonium ion in acidic media (i.e., $\mathrm{H}_{2} \mathrm{O}$ or methanol). ${ }^{30}$

The kinetics for the reaction of nucleophiles with arene oxides have not been examined in order to differentiate between the possibilities of: (i) direct nucleophilic attack by RS ${ }^{-}$upon epoxide carbon or a tight ion pair, ${ }^{32}$ and (ii) the trapping by $\mathrm{RS}^{-}$of the carbonium ion species generated after the rate-determining step in aromatization (Scheme IV). The trapping of a resonantly stabilized carbonium ion formed along a reaction path has precedence. As an example, one may sight the trapping of the transient oxocarbonium ion formed on hydrolysis of methyl orthobenzoate by hydroxylamine and semicarbazide to yield the corresponding methyl imidate esters. ${ }^{31}$ Stereochemical arguments against the mechanism of eq 29 based on the formation of

trans adduct in the reaction of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~S}^{-}$with BO (loc. cit.) are not completely convincing since shielding in the carbonium ion by the $-\mathrm{O}^{-}$or -OH substituent to approach by the bulky $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~S}^{-}$is most likely. The extent of this shielding to cis addition is difficult to surmise. However, the fact that the disappearance of BO (Figure 1) from solution is first order in [RS ${ }^{-}$] species rules out the possibility of the trapping by $\mathrm{RS}^{-}$of the carbonium ion formed in the rate-determining step of the NIH shift (eq 29). For the aromatization reaction, the possibility of the formation of a tight internal ion pair $\left(\mathrm{O}^{-} \mathrm{C}^{+}\right)$, whose partitioning to BO and carbonium ion ( $\mathrm{OH} \mathrm{C}{ }^{+}$) is partially rate determining, must be taken into account (eq 30, Figure 4). One might, therefore, con-

Figure 5. Hypothetical reaction coordinate diagram for the aromatization of benzene oxide in solvents of high (lower curve) and low (upper curve) dielectric constants. The species $\left\{\mathrm{O}^{-} \mathrm{C}^{+}\{\right.$represents an internal ion pair whereas $\left\{\mathrm{O}^{-} \mathrm{C}^{+}\right\}$and $\} \mathrm{HO} \mathrm{C}^{+}\{$represent carbonium ion species; the latter being formed from the former by diffusion-controlled proton transfer from water.

sider if it is reasonable that $\mathrm{RS}^{-}$intercepts the ion-pair species. Sneen ${ }^{32}$ has presented arguments in support of tight ion pairs as intermediates in SN2 displacements, and it is conceivable that such a species could be common to both the reaction of $\mathrm{RS}^{-}$with BO and the aromatization of the latter. A decrease in the dielectric constant accompanying the incorporation of organic solvent would provide less destablization to the ion pair since it is a zwitterion, ${ }^{33}$ than to the carbocation (Figure 5). The result would be (as seen ${ }^{27}$ ) to decrease the rate of the aromatization reaction with little effect on the rate of addition.

In Figure 6 there is plotted, in the Bronsted fashion, the logarithms of the second-order rate constants for the reaction of $\mathrm{RS}^{-}$species with $\mathrm{A}^{+}, \mathrm{BO}$, and ethylene oxide ${ }^{22}$ vs. the $\mathrm{p} K_{\mathrm{a}}$ of RSH. Examination of Figure 6 reveals that the $\beta_{\text {nuc }}$ values for reactions of $\mathrm{RS}^{-}$with ethylene oxide ( $20^{\circ}$ ) and BO and $\mathrm{A}^{+}\left(30^{\circ}\right)$ are comparable. The small $\beta_{\text {nuc }}$ values indicate that the basicity of the RS ${ }^{-}$species exhibited toward the proton has little to do with the nucleophilicity of RS ${ }^{-}$toward either substrate. The value of $\beta_{\text {nuc }}$ for the reaction of RS ${ }^{-}$species with BO, the delocalized carbonium ion of $\mathrm{A}^{+}$, and ethylene oxide ${ }^{34}$ is comparable to $\beta_{\text {nuc }}$ for reaction of amines ${ }^{35}$ with $A^{+}$. This feature and the similarity in the rate constants for reaction of RS ${ }^{-}$species with BO and ethylene oxide may be interpreted as suggesting similar intimate ion trapping mechanisms. The mechanisms of aliphatic epoxide ring opening has received considerable attention. The weight of evidence supports either direct nucleophilic displacement or displacement through a tight ion pair. ${ }^{32}$ Thus, for water attack, ${ }^{36}$ the importance of the activity of $\mathrm{H}_{2} \mathrm{O}$ in aqueous organic solvents, volumes of activation, ${ }^{37}$ entropies of activation, and deuterium solvent kinetic isotope effects supports best an "SN2" reaction. The reaction of $\mathrm{HO}^{-}, \mathrm{EtO}^{-}, \mathrm{MeO}^{-}, \mathrm{AcO}^{-}$, and $\mathrm{Cl}^{-}$with aliphatic oxides are all first order in the nucleophile, yield

Figure 6. Bronsted plot for reaction of thiol anion species with ethylene oxide (EO) at $20^{\circ}$, benzene oxide (BO) at $30^{\circ}$, and the unprotonated species of malachite green $\left(\mathrm{A}^{+}\right)$at $30^{\circ}$.
products accountable by substitution on primary in preference to secondary carbon, and provide Walden inverted products. ${ }^{36} 38-40$ The differentiation between an SN2 reaction and displacement upon an internal ion pair is not readily made. As an example, the near identity of the rate constants for attack of $\mathrm{RS}^{-}$upon $\mathrm{BO}\left(30^{\circ}\right)$ and ethylene oxide $\left(20^{\circ}\right)$ may be explained by either mechanism. The internal ion pair formed from BO would be more stable, due to delocalization of the positive charge, than that from ethylene oxide. However, nucleophilic addition to the resonantly stabilized internal pair formed from BO should be slower than attack upon the localized charge of the internal pair formed from ethylene oxide. The reactions of $\mathrm{RS}^{-}$with MG serve as an example of nucleophilic addition to a resonantly stabilized carbonium ion. The second-order rate constants are certainly less than one would anticipate for attack on a carbocation. One could argue that the compensation between internal ion pair stability and susceptibility to nucleophilic attack could make the second-order rate constants for reaction of $\mathrm{RS}^{-}$with BO and ethylene oxide similar. In any event, one must conclude that the mechanism for reaction of $\mathrm{RS}^{-}$with the epoxides of ethylene and benzene are mechanistically akin.

The second-order rate constants for the reaction of amines with ethylene oxide vary from $\sim 10^{-3}$ to $\sim 10^{-5} \mathrm{M}^{-1}$ $\mathrm{sec}^{-1}$ on change of the $\mathrm{p} K_{\mathrm{a}}$ of the related ammonium ions from $\sim 4$ to $\sim 11 .{ }^{41}$ If the second-order rate constants for reaction of amines with BO are similar to those for ethylene oxide, as is the case with thiol anions, then no reaction would be seen with BO. This is due to the fact that the aromatization of BO would predominate. Though the reactivity of BO and ethylene oxide toward nucleophiles may be similar, the spontaneous disposition of BO is through aromatization while that for ethylene oxide is nucleophilic addition of water. The spontaneous rate for BO is $\sim 10^{3}$ great$\mathrm{er}^{27}$ than that for ethylene oxide. ${ }^{36,37,42,43}$ Thus, the fact that ethylene oxide is subject to nucleophilic attack by weaker nucleophiles than is BO is simply due to the fact that ethylene oxide remains in solution longer. The secondorder rate constants determined for the reaction of $\mathrm{RS}^{-}$ species with BO are just sufficiently large to allow their determination over the competing aromatization reaction (Figure 1). The $\beta_{\text {nuc }}$ value for reaction of amines with ethylene oxide is ca. 0.3 . If the same were true for reaction of
amines with BO, then one might predict that nucleophilic addition of amines might be seen in the case of electron-deficient benzene oxides. Under these restrictions, the aromatization reaction would be greatly slowed $(\rho \simeq-7) .{ }^{28}$ This possibility is presently under investigation.

Note Added in Proof. The prediction that electron withdrawing substituents should allow nucleophilic attack by amines on BO has been fulfilled in the observation of nucleophilic catalysis of the aromatization of 4 -carbo-tertbutoxybenzene oxide by amines and the isolation and proof to structure (NMR) for the 3-trans adduct of trimethylamine [see communication by D. M. Johnson and T. C. Bruice, J. Am. Chem. Soc., 97, 6901 (1975)].
