the reaction rate, compared with $\mathrm{Cu}^{2+}$, it is suggested that this is enough, but also that both of these binding sites are used for coordination to the triphosphate chain. As the reaction most probably proceeds also in this case via an intramolecular nucleophilic $\mathrm{OH}^{-}$attack from a M-OH unit (section 3), one may tentatively suggest the following structure and mechanistic path for the reactive $\left[(\operatorname{tn})_{2} \mathrm{Co}(\mathrm{OH})(\mathrm{ATP}) \mathrm{Cu}(\mathrm{bpy})\right]^{0}$ species: $\mathrm{Cu}-$ (bpy) ${ }^{2+}$, coordinating to the $\alpha, \beta$ phosphate group of ATP ${ }^{4}$, leads to ring-opening of the cobalt chelate and to a monodentate coordination of $(\mathrm{tn})_{2} \mathrm{Co}(\mathrm{OH})^{2+}$ at the $\gamma$ group, thus allowing for an intramolecular attack at the $\gamma$ phosphorus by the cobalt-bound $\mathrm{OH}^{-}$.

In conclusion, it is evident that systems containing two different metal ions can also be rather reactive toward the dephosphorylation
of nucleoside $5^{\prime}$-triphosphates. This observation corresponds to many biological phosphoryl and nucleotidyl transfers, where two different metal ions are also often involved. ${ }^{9,10}$

# Crystal and Solution Structures of cyclo(Ala-Pro-Gly-D-Phe-Pro): A New Type of Cyclic Pentapeptide Which Undergoes Cis-Trans Isomerization of the Ala-Pro Bond 

Lila M. Gierasch, ${ }^{* \dagger}$ Isabella L. Karle, ${ }^{* \dagger}$ Arlene L. Rockwell, ${ }^{\dagger}$ and Kemal Yenal ${ }^{\dagger}$<br>Contribution from the Department of Chemistry, University of Delaware, Newark, Delaware 19716, and the Laboratory for the Structure of Matter, Naval Research Laboratory, Washington, D.C. 20375. Received September 13, 1984

#### Abstract

L-Ala-L-Pro-Gly-D-Phe-L-Pro) has been synthesized and its conformation determined in the crystalline state and in solution in chloroform and dimethyl sulfoxide. This cyclic pentapeptide was designed to explore the conformational response of the restricted pentapeptide ring to the presence of an $L$ residue preceding proline; it is the first cyclic pentapeptide with an LldDL chiral sequence to be studied. In crystals, a cis Ala-Pro bond exists, and there are no intramolecular hydrogen bonds. The Ala NH is buried in the interior of the backbone ring and does not participate in any hydrogen bonding. In both prolines, the $\mathrm{C}^{\gamma}$ atom is disordered between at least two positions corresponding to two different envelope conformations for the pyrrolidine ring. The peptide crystallizes in the orthorhombic space group $P_{2} 2_{1} 2_{1}$ with cell parameters $a=9.142$ (2) $\AA, b=11.000$ (4) $\AA$, and $c=23.885(5) \AA$. In solution in dimethyl sulfoxide, the same one-cis form of the peptide is observed, but a conformational change occurs to an all-trans form in chloroform. There appear to be hydrogen-bonding interactions within the ring in the all-trans form, but they are not well-defined. The most likely conformation based on proton and carbon NMR data for the all-trans form contains a type II Pro-Gly $\beta$ turn within which is a weak $\gamma$ turn with a hydrogen bond between the Gly NH and the Ala $\mathrm{C}=\mathrm{O}$.

Cyclic pentapeptides have been extensively studied as conformational models, particularly for reverse turns. ${ }^{1-8}$ In cases where both solution and crystal structure analyses have been carried out (Table I), an all-trans conformation containing an internal $4 \rightarrow$ 1 hydrogen bond in a type I or II $\beta$ turn and often an internal $3 \rightarrow 1$ hydrogen bond in a $\gamma$ turn is observed for this family of peptides. Yet all these examples fall into a single class of backbone sequence chirality: DLldL or its mirror image LDLLD (with Gly residues occupying either L or D sites).
The peptide cyclo(Ala-Pro-Gly-D-Phe-Pro) (all residues are of the L configuration unless otherwise noted) was originally designed to explore a question raised in the solution conformational analysis of cyclo(Gly ${ }^{1}$ - $\mathrm{Pro}^{2}$-Gly ${ }^{3}$-D-Ala ${ }^{4}$-Pro ${ }^{5}$ ). ${ }^{2}$ While a predominant all-trans conformer with both $\beta$ and $\gamma$ turn intramolecular hydrogen bonds exists for this latter peptide in several solvents, a small proportion ( $<20 \%$ ) of a conformer containing one-cis peptide bond is observed in water. Complexation with cations perturbs the conformational distribution, leading to higher proportion of the one-cis form. Model building led to the proposal that it is the Gly'-Pro ${ }^{2}$ bond that undergoes isomerization in cyclo(Gly-

[^0]Pro-Gly-d-Ala-Pro). Furthermore, introduction of an L residue in place of Gly ${ }^{1}$ was predicted to favor the one-cis form; replacement of Gly ${ }^{1}$ with a D residue was predicted to preclude formation of the one-cis form. These predictions have been substantiated by synthesis of the title peptide and by synthesis and conformational analysis of cyclo(D-Phe-Pro-Gly-D-Ala-Pro). No cis form has been seen for this latter peptide, even upon complexation by cations. ${ }^{11}$ A complete conformational analysis

of cyclo(D-Phe-Pro-Gly-D-Ala-Pro) by quantitative nuclear Overhauser effect spectroscopy has been reported. ${ }^{12}$ Preliminary studies of cation complexation by cyclo(Ala-Pro-Gly-D-Phe-Pro) showed the predicted strong preference for a one-cis conformation. ${ }^{11}$

The preferred conformations of cyclo(Ala-Pro-Gly-D-Phe-Pro) are described in the present paper. Indeed, in solution this peptide readily undergoes a conformational change from an all-trans form preferred in chloroform (70:30) to a one-cis Ala-Pro conformer preferred in dimethyl sulfoxide ( $\sim 100 \%$ ). In the crystalline state, this cyclic pentapeptide takes up the one-cis form. Presence of an L substituent preceding Pro and existence of a different chiral sequence have major effects on the preferred conformation of cyclic pentapeptides.

## Experimental Section

Synthesis. Procedures used in the synthesis of cyclo(Ala-Pro-Gly-D-Phe-Pıo) were as previously described. ${ }^{2,4}$ Peptide bond couplings were accomplished by the mixed anhydride method, using $N$-methylmorpholine and isobutyl chloroformate. N-termini were protected by the tert-butyloxycarbonyl ( $t$-Boc) group and C-termini by formation of a benzyl ester. Deprotection of the former was by treatment with HCl in anhydrous ether and of the latter by hydrogenation in the presence of a Pd/carbon catalyst. Precursors were crystallized whenever possible, and their identity and purity checked by thin-layer chromatography, ${ }^{1} \mathrm{H}$ NMR, infrared spectroscopy, and melting point determination. The pentapeptide was cyclized as the $p$-nitrophenyl ester, which was formed by coupling the pentapeptide acid and $p$-nitrophenol by using dicyclohexylcarbodiimide. Removal of the $t$-Boc group yielded an amorphous solid ( 2.72 g from $3.08 \mathrm{~g}, 97 \%$ ) which was dissolved in acidified dimethylformamide ( 63 mL ) and added (dropwise) over 3 h to spectral grade pyridine ( 800 mL , dried over alumina) and stirred at $50^{\circ} \mathrm{C}$ for 3 days. Removal of the pyridine yielded a yellowish oil that was dissolved in $50: 50$ ethanol/water ( 100 mL ) and treated with Rexyn I-300 mixedbed ion-exchange resin ( 10 g ) for several hours. Evaporation of the solvent and trituration with ether yielded a crude product ( $1.36 \mathrm{~g}, 70 \%$ yield, $\sim 90 \%$ pure); a portion of this material was subsequently crystallized from methylene chloride/ether: mp 144-149 ${ }^{\circ} \mathrm{C}, R_{f}(93: 7$, $\left.\mathrm{CHCl}_{3} / \mathrm{CH}_{3} \mathrm{OH}\right)=0.50$. Appropriate ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR spectra were observed; the identity and the monomeric nature of the peptide were con-

${ }^{a}$ The esd's for $x, y$, and $z$ are near $0.0009,0.0008$, and 0.0003 , respectively, for the backbone atoms and increase up to $0.0020,0.0018$, and 0.0009 for some of the atoms in the side groups. ${ }^{b} B_{\text {eq }}=$ $4 / 3 \sum_{i} \sum_{j} \beta_{i j} a_{i} a_{j}$.
firmed by mass spectrometry ( $m / e$ obsd for $\mathrm{C}_{24} \mathrm{H}_{31} \mathrm{~N}_{5} \mathrm{O}_{5} 469.232$, predicted 469.232).
X-ray Crystallography. Clear, colorless crystals were grown from $\mathrm{CH}_{3} \mathrm{CN}$. X-ray intensity data were collected from a platelet of dimensions $0.28 \times 0.35 \times 0.08 \mathrm{~mm}$ by using an automatic four-circle diffractometer in the $\theta / 2 \theta$ scan mode and a variable scan speed dependent upon the intensity. Data were collected with $\mathrm{Cu} \mathrm{K} \alpha$ radiation and a graphite monochromator. During the data collection, reflections 032,1113 and 506 , serving as monitors and remeasured at intervals of 60 measurements, did not indicate any decay. The data were corrected for Lorentz and polarization effects, and normalized $|E|$ values were obtained by means of a $K$ curve. The space group is $P 2_{1} 2_{1} 2_{1}$ with cell parameters $a=9.142$ (2) $\AA, b=11.000$ (4) $\AA, c=23.885$ (5) $\AA, Z=4, V=2401.9 \AA^{3}$, and a calculated density of $1.298 \mathrm{~g} \mathrm{~cm}^{-3}$ for the molecular formula $\mathrm{C}_{24} \mathrm{H}_{31}-$ $\mathrm{N}_{5} \mathrm{O}_{5}$ and a molecular weight of 469.54 .

${ }^{a}$ Estimated standard deviations are of the order of $0.010 \AA$ for bond lengths and $0.7^{\circ}$ for bond angles in the peptide ring and increase up to $0.03 \AA$ for bond lengths and $1.7^{\circ}$ for bond angles in some of the side groups. ${ }^{b}$ Elongated ellipsoids for the thermal parameters of some of the atoms in the side groups of $\mathrm{Pro}^{2}, \mathrm{D}-\mathrm{Phe}^{4}$, and Pro indicate positional disorder for these atoms. The bond lengths and angles listed represent a nonphysical model that is an average of several conformations.

The structure of the crystal was solved by determining phases directly from the intensities. After initial refinement with full-matrix least squares of the $34 \mathrm{C}, \mathrm{N}$, and O atoms and anisotropic thermal parameters, hydrogen atoms were placed in idealized positions. Further least-squares refinement, holding the coordinates for the hydrogen atoms constant, resulted in an agreement factor of $R=8.4 \%$ for 1544 reflections with $|F|_{\text {cbsd }}>2$ and $R_{\mathrm{w}}=7.0 \%$ for all 1817 data. The somewhat high $R$ values can be correlated with local disorder and high thermal values for the side groups in the Pro and D-Phe residues. The structure of the molecule is depicted in the computer drawing in Figure 1. The coordinates for the $\mathrm{C}, \mathrm{N}$, and O atoms are listed in Table 1I, bond lengths and angles are shown in Table III, and conformational angles are shown in Table IV.

NMR Spectroscopy. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were obtained in the Fourier transform mode on Bruker WM250 or AM250 spectrometers operating at 250.13 MHz for ${ }^{1} \mathrm{H}$ and 62.90 MHz for ${ }^{13} \mathrm{C}$. Samples were referenced to internal tetramethylsilane. Deuterated solvents were purchased from Cambridge Isotopes. Two-dimensional spectra (COSY and NOESY) were obtained by using standard Bruker software.

## Results and Discussion

Conformation in the Crystal State. The conformation of $c y$ clo(Ala ${ }^{1}-\mathrm{Pro}^{2}-\mathrm{Gly}^{3}$-D- $\mathrm{Phe}^{4}-\mathrm{Pro}^{5}$ ) in crystals is shown in Figure 1. For purposes of comparison, the crystal conformation of a similar peptide with a D residue in place of the L-Ala of the title peptide is shown in Figure 2. An immediately obvious difference is the occurrence of a cis peptide bond between $\mathrm{Ala}^{1}$ and $\mathrm{Pro}^{2}$ in Figure 1. As a result of the cis bond, $\mathrm{O}_{1}$ is directed to the exterior of the backbone ring and cannot participate in an intramolecular hydrogen bond with $\mathrm{N}_{4} \mathrm{H}$. A difference of $57^{\circ}$ in $\psi_{5}$ has changed the direction of $\mathrm{O}_{4}$ away from $\mathrm{N}_{1} \mathrm{H}$ so that the resulting geometry

${ }^{a}$ The convention followed for labeling atoms and conformational angles is that proposed by the IUPAC-IUB Comission on Biochemical Nomenclature (Biochemistry 1970, 9, 3741-3479). In the fully extended chain $\phi_{i}=\psi_{i}=\omega_{i}=180^{\circ}$. ${ }^{b}$ Esd's for the torsional angles are near $1.4^{\circ}$. ${ }^{c}$ The $\mathrm{C}^{\gamma}$ atoms in pyrrolidine rings in $\mathrm{Pro}^{2}$ and $\mathrm{Pro}^{5}$ are highly disordered (see text) representing two possible envelope conformations. The angles listed are for a nonphysical model of the average of the different conformations.

Figure 2. Diagram of cyclo(D-Phe-Pro-Gly-D-Ala-Pro), having a typical backbone conformation for a DLDDL sequence. ${ }^{5}$ Note that the Gly residue has assumed $\phi, \psi$ angles characteristic for a D residue.
in the molecule in Figure 1 is inappropriate for forming a $3 \rightarrow$ 1 hydrogen bond ( $\gamma$ turn) as exists in the molecule in Figure 2. Furthermore, the $\mathrm{N}_{1} \cdots \mathrm{O}_{4}$ distance in Figure 1 is $3.29 \AA$. In fact, $\mathrm{N}_{1}$ is buried in the interior of the present molecule and does not participate in any hydrogen bond formation, intra- or intermolecular.

The substitution of an $L$ residue for a $D$ residue in position 1 makes the conformation shown in Figure 2 untenable for steric reasons. Space-filling models show a collision between the methyl side chain in $\mathrm{Ala}^{1}$ and $\mathrm{O}_{5}$ as well as $\mathrm{C}_{2}{ }^{\delta}$ of the $\mathrm{Pro}^{2}$ residue.

Bond angles differ for the cis- $\mathrm{Pro}^{2}$ and trans- $\mathrm{Pro}^{5}$ residues. For example, $\mathrm{C}_{1} \mathrm{~N}_{2} \mathrm{C}_{2}$ is $127.6^{\circ}$ while $\mathrm{C}_{4} \mathrm{~N}_{5} \mathrm{C}_{5}$ is only $120.2^{\circ}$ (Table IV). This difference is consistent with the difference in values of bond angles observed for cis and trans residues in other peptides. ${ }^{13,14}$

An examination of the "thermal"parameters, represented in Figure 1 by ellipsoids at the $50 \%$ probability level and listed in the $B_{\text {eq }}$ column in Table II, shows that very large ellipsoids are associated with $\mathrm{C}^{\gamma}$ atoms in the two Pro residues and in the outermost atoms of the D-Phe residue. The thermal ellipsoids represent not only the natural vibrations of the atoms but also positional disorder of the atoms from molecule to molecule in the crystal. The elongated ellipsoids for the $\mathrm{C}_{2}{ }^{\gamma}$ and $\mathrm{C}_{5}{ }^{\gamma}$ atoms in the two pyrrolidine rings indicate puckering disorder. Within each ellipsoid there are two different positions for each of these atoms which correspond to the two envelope conformations that are endo and exo with respect to the interior of the backbone ring of the peptide. The thermal ellipsoids for the phenyl ring in D -Phe ${ }^{4}$, seen from different vantage points in Figures 1 and 3, increase in elongation from $\mathrm{C}_{4}{ }^{\gamma}$ to $\mathrm{C}_{4}{ }^{\eta}$. The relative size and orientation of the ellipsoids suggest the presence of different rotamers for the phenyl ring in the different unit cells. The different orientations may be produced by small rotations about the $\mathrm{C}_{4}{ }^{\alpha}-\mathrm{C}_{4}{ }^{\beta}$ bond and

|  | $\mathrm{CDCl}_{3}$ |  | 22.19 |  |  | 25.01 |

${ }^{a}$ Unless noted otherwise, $25^{\circ} \mathrm{C}, 5 \mathrm{mg} / 0.5 \mathrm{~mL}$ in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}, 20$ $\mathrm{mg} / 0.5 \mathrm{~mL}$ in $\mathrm{CDCl}_{3}, 250 \mathrm{MHz}\left({ }^{1} \mathrm{H}\right), 62.9 \mathrm{MHz}\left({ }^{13} \mathrm{C}\right)$. Chemical shifts in ppm downfield from internal tetramethylsilane. Where measurable, parameters are given in both $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ and $\mathrm{CDCl}_{3}$. Upfield region of spectrum in $\mathrm{CDCl}_{3}$ was highly overlapped due to $30: 70$ mixture of one-cis and all-trans conformers. ${ }^{b}$ Parts per billion/deg temperature range $22-110^{\circ} \mathrm{C}\left(\mathrm{Me}_{2} \mathrm{SO}\right), 22-52^{\circ} \mathrm{C}\left(\mathrm{CDCl}_{3}\right) .{ }^{c}$ Under the aromatics, estimated maximum slope. ${ }^{d}$ Centers of multiplets; rough positions in many cases from two-dimensional correlated spectra. ${ }^{e}$ Proline assignments are not definitive; those presented are based on comparisons with other pentapeptides.
small rotations about the $\mathrm{C}_{4}{ }^{\beta}-\mathrm{C}_{4}{ }^{\gamma}$ bond. The multiple conformations for the side groups in this structure are possible owing to the relatively large space in the unit cell surrounding each of these groups, thus giving them some freedom of motion. The packing diagram of the molecules in the crystal lattice, illustrated in Figure 3, shows that the pyrrolidine and phenyl rings are adjacent to voids where the nearest approaches across the voids are greater than $4.0 \AA$.
The stability of the lattice is maintained by pairs of hydrogen bonds that link adjacent molecules firmly into zigzag ribbons. The hydrogen bonds are between $\mathrm{N}_{3} \ldots \mathrm{O}_{5}(3.007 \AA)$ and $\mathrm{N}_{4} \ldots \mathrm{O}_{1}(2.907$ $\AA$ ) in molecules related by the twofold screw operations parallel to the $b$ axis. Relatively weaker van der Waals' attractions between hydrophobic groups hold the ribbons of molecules together. For example, in the $a$ direction, that is, perpendicular to the view in Figure 3, there are attractions between the methyl group of Ala ${ }^{1}$ and the pyrrolidine ring of $\mathrm{Pro}^{2}$ in the molecule directly underneath where $\mathrm{C}_{1} \cdots \mathrm{C}_{2}$ is $3.93 \AA$, and between the pyrrolidine ring of $\mathrm{Pro}^{5}$ and the phenyl ring of D-Phe ${ }^{4}$ from a molecule in an adjacent ribbon (see the middle of Figure 3) where $\mathrm{C}_{4} \cdots \mathrm{C}_{5}$ is 3.54 $\AA$.

Conformations in Solution. The preferred conformation of this cyclic pentapeptide in dimethyl sulfoxide $\left(\mathrm{Me}_{2} \mathrm{SO}-d_{6}\right)$ retains the

Figure 4. Upfield regions of $62.9-\mathrm{MHz}{ }^{13} \mathrm{C}$ NMR spectra of cyclo-(Ala-Pro-Gly-D-Phe-Pro) (a) $\mathrm{Me}_{2} \mathrm{SO}-d_{6}, 40 \mathrm{mg} / \mathrm{mL}$, and (b) in $\mathrm{CDCl}_{3}$, $40 \mathrm{mg} / \mathrm{mL}$. Temperature $25^{\circ} \mathrm{C}$. In (b), resonances for the one-cis conformer are labeled " $c$ " and those of the all-trans conformer " $t$ ".
principal features of its conformation in the crystal state: a cis peptide bond between L-Ala ${ }^{1}$ and L-Pro ${ }^{2}$ and an unusual buried Ala NH that is not intramolecularly hydrogen bonded. Evidence supporting this conformation includes the following: (1) A ${ }^{13} \mathrm{C}$ NMR spectrum of the peptide reveals the characteristic pattern of proline $\mathrm{C}^{\beta}$ and $\mathrm{C}^{\gamma}$ resonances for one cis and one trans X -Pro bond (Figure 4a). (2) ${ }^{1} \mathrm{H}$ NMR data for this peptide in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ (Table V) indicate that the Ala NH is inaccessible to intermolecular interactions (small $\Delta \delta / \Delta T$ ) but resonates at a high chemical shift, consistent with little or no hydrogen bonding. (3) A sizable nuclear Overhauser effect was observed between Ala ${ }^{1}$ $\mathrm{H}^{\alpha}$ and the downfield Pro $\mathrm{H}^{\alpha}$ resonances, as expected for a cis Ala-Pro bond. (4) The D-Phe and Gly NH's behave as though they are solvated by $\mathrm{Me}_{2} \mathrm{SO}$ molecules (high $\Delta \delta / \Delta T$, low $\delta$ ).

A comparison in greater detail between the crystal conformation of cyclo(Ala-Pro-Gly-D-Phe-Pro) and its conformation in

Figure 5. Downfield (amide) regions of $250-\mathrm{MHz}^{1} \mathrm{H}$ NMR spectra of cyclo(Ala-Pro-Gly-D-Phe-Pro). Representative points during a $\mathrm{CDCl}_{3} / \mathrm{Me}_{2} \mathrm{SO}-d_{6}$ titration (percentage given as $v / v$ ) of the pentapeptide are shown. Concentration $5 \mathrm{mg} / 0.5 \mathrm{~mL}$. Temperature $25^{\circ} \mathrm{C}$. (a) $100 \%$ $\mathrm{CDCl}_{3}$; (b) $85 \% \mathrm{CDCl}_{3}, 15 \% \mathrm{Me}_{2} \mathrm{SO}-d_{6}$; (c) $100 \% \mathrm{Me}_{2} \mathrm{SO}-d_{6}$. Resonances from the one-cis conformer are labeled " $c$ " and those from the all-trans conformer " $t$ ".
$\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ suggests that there may be some minor rearrangements or averaging in solution. Observed vicinal coupling constants ( $J_{\mathrm{NH}-\mathrm{H}^{\alpha}}$ ) differ from those expected if the crystal conformation were strictly retained in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$. For example, $J_{\mathrm{NH}-\mathrm{H}^{\alpha}}$ for Ala ( 4.5 Hz ) can be attributed to a $\phi$ dihedral angle of ca. $100^{\circ}$, while the X-ray derived $\phi$ angle ( $69^{\circ}$ ) would be expected to show a $J_{\mathrm{NH}-\mathrm{H}^{\alpha}}$ of $6-8 \mathrm{~Hz} .^{15}$ Conformational averaging around $\phi$ would be expected to reduce the observed coupling constant, since the X-ray derived $\phi$ is near a maximum in the $J$ vs. $\phi$ function.

Model building together with fitting of observed NMR parameters yields a possible conformation for the one-cis form of cyclo(Ala-Pro-Gly-D-Phe-Pro) in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ :

|  | Ala | Pro | Gly | D-Phe | Pro |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $\phi$ | 100 | -80 | $\sim 90$ | 120 | -80 |
| $\psi$ | 120 | 160 | 80 | -100 | 0 |

The glycine $J_{\mathrm{NH}-\mathrm{H}^{\alpha}}$ values ( 4.6 and 6.3 Hz ) suggest some degree of averaging around this residue. Note from Table V that the NMR parameters for the one-cis form present as $30 \%$ of the conformational distribution in $\mathrm{CDCl}_{3}$ are somewhat different from those in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$. Hence, while the same peptide bond states of isomerization obtain, perturbations around the backbone have occurred in this weakly hydrogen-bond-donating solvent. For example, the Ala $J_{\mathrm{NH}-\mathrm{H}^{\alpha}}$ coupling constant is less than 2 Hz , suggesting an Ala $\phi$ angle close to $120^{\circ} .{ }^{15}$ The region of the structure around this Ala residue is extremely strained and crowded; there is no arrangement, given the constraints of cyclization, that seems devoid of unfavorable contacts. Not only is the Ala methyl sterically hindered by the carbonyl oxygens of Pro ${ }^{5}$ and Ala ${ }^{1}$, but also these two oxygens are subject to close

[^2]

Figure 6. Plot of $\mathrm{CDCl}_{3} / \mathrm{Me}_{2} \mathrm{SO}-d_{6}$ titration data: NH resonances as a function of solvent composition. The cross-hatched band indicates the position of the aromatic resonances. Open symbols: all-trans conformer; filled symbols: one-cis conformer.
approach given certain combinations of dihedral angles (as in the crystal).
The conformational lability of this constrained peptide is illustrated further by its response to a change of solvent. As shown in Figure 4 b , the ${ }^{13} \mathrm{C}$ NMR spectrum of cyclo(Ala-Pro-Gly-D-Phe-Pro) in $\mathrm{CDCl}_{3}$ displays Pro $\mathrm{C}^{\beta}$ and $\mathrm{C}^{\gamma}$ resonances indicative of two populations of slowly interconverting conformers: one, all-trans, present in $70 \%$ proportion and the other, one-cis, making up the remaining $30 \%$. Titration of the peptide in $\mathrm{CDCl}_{3}$ with $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ confirms that the minor form present in $\mathrm{CDCl}_{3}$ has the same arrangement of peptide bond configurations as the major form in $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ (Figures 5 and 6). Spectral parameters for this one-cis form are presented in Table $V$, and its conformation is discussed above.
The other form present in $\mathrm{CDCl}_{3}$ has all-trans peptide bonds, as judged by its ${ }^{13} \mathrm{C}$ NMR spectrum (Figure 4b). The complexity of ${ }^{1} \mathrm{H}$ NMR spectra for the pentapeptide in $\mathrm{CDCl}_{3}$ presents problems for analysis of the all-trans form. Two-dimensional NMR spectroscopy was used to separate and assign the resonances of the two interconverting conformers. $J$-coupled spin systems were analyzed by using two-dimensional correlated (COSY) spectra, in which the normal one-dimensional spectrum appears along the diagonal (usually presented as a contour plot) and cross-peaks occur at the intersections of chemical shifts for two $J$-coupled resonances. The COSY spectrum for cyclo(Ala-Pro-Gly-D-Phe-Pro) in $\mathrm{CDCl}_{3}$ is shown in Figure 7. The strength of the two-dimensional method of spectral analysis is clearly demonstrated in this example of a highly overlapped mixture of conformers. Another two-dimensional NMR experiment, the NOE-correlated or NOESY spectrum (not shown), was very informative in this study. Resonances that exchange spin polarization by dipole-dipole interactions, usually through space, give rise to cross-peaks in NOESY spectra. Alternatively, spin polarization can be transferred by chemical exchange, provided that chemical exchange occurs slowly relative to the rate of polarization transfer. Here, resonances arising from one of the two slowly interconverting conformers give rise to cross-peaks with corresponding resonances in the other conformer. By analyzing these results, the assignments to the one-cis or all-trans form were confirmed. When these approaches were used, the key spectral data (given in Table VI) were obtained, and taken as a whole, they lead to a consistent overall model. There is a suggestion of some conformational dependence on concentration, temperature, or solvent. Spectral parameters for the NH resonances indicate that the D-Phe and Ala NH's are less accessible to intermolecular interactions than is the Gly NH, but the Ala NH appears not to be intramolecularly hydrogen-bonded. Evidence for this interpretation includes the following: (1) the higher chemical shift of the Ala NH than those of the D-Phe and the Gly in pure $\mathrm{CDCl}_{3}$

Figure 7. Two-dimensional correlated (COSY) spectrum of cyclo(Ala-Pro-Gly-D-Phe-Pro) in $\mathrm{CDCl}_{3}$. For reference the one-dimensional spectrum is shown across the top. The spin systems for Ala, D-Phe, and Gly residues in each conformer are connected by dashed (one-cis conformer) or solid (all-trans conformer) lines. These data were obtained by using standard Bruker software, with a $90-t_{1}-90$ acquire sequence, 2048 points zero-filled to 4096 in F2, number of $t_{1}$ 's 256 , were zero-filled to 512 points in F1, number of scans 96 , sine-bell apodization in both dimensions. Peptide concentration $20 \mathrm{mg} / 0.5 \mathrm{~mL}$. Note that in two dimensions, adequate resolution is achieved to identify all the Ala, D-Phe, and Gly resonances. Examination of rows in the two-dimensional matrix enabled rough measurement (resolution 2.4 Hz /point) of $J_{\mathrm{NH}-\mathrm{H}^{a}}$ for the Gly residues and $J_{\mathrm{H}^{\alpha}-\mathrm{H}^{\beta}}$ for the D-Phe residues (Tables V and VI).
(at concentrations dilute enough to prevent intermolecular effects);
(2) the small, positive $\Delta \delta / \Delta T$ of the Ala NH which contrasts with the negative $\Delta \delta / \Delta T$ of the D -Phe, which in turn has a smaller magnitude than that of the Gly (also negative); and (3) the shifts caused by addition of $\mathrm{Me}_{2} \mathrm{SO}$ to a $\mathrm{CDCl}_{3}$ solution of the peptide-greater for the Gly than the D-Phe NH resonances, which were both apparently larger than the shifts of the Ala NH resonance (Figure 6). The unusual positive $\Delta \delta / \Delta T$ of the Ala NH and small changes in coupling constants (upon solvent titration) indicate some degree of conformational change.

The ${ }^{13} \mathrm{C}$ NMR spectrum of the cyclic pentapeptide in $\mathrm{CDCl}_{3}$ (Figure 4 b ) has an unusual pattern of Pro $\mathrm{C}^{\beta}$ and $\mathrm{C}^{\gamma}$ resonances for the all-trans conformer. One $\mathrm{C}^{\gamma}$ signal is at lower field, and one $\mathrm{C}^{\beta}$ signal is at higher field than typical "unconstrained" values.

Although unique assignments of carbon signals to particular prolines in the sequence are not possible, these positions are reminiscent of proline signals in the all-trans conformers of the cyclo(L-X-Pro-D-Y[Gly] $)_{2}$ hexapeptides, which, like this cyclic pentapeptide, undergo a cis-trans isomerization. ${ }^{16}$ In the case of the cyclic hexapeptides, consideration of a variety of spectral data led to a proposal of a bifurcated hydrogen bond: a $\gamma$ turn within a $\beta$ turn, where two NH's, the NH's of the $(i+2)$ th and the $(i+3)$ th residues in the $\beta$ turn, both interact with the $\mathrm{C}=\mathrm{O}$ of the $i$ th residue. ${ }^{16}$ This arrangement, coupled with the presence of an L-residue preceding Pro, may be correlated with the unusual

${ }^{a}$ Unless otherwise noted, $25^{\circ} \mathrm{C}$ and $20 \mathrm{mg} / 0.5 \mathrm{~mL}, 250 \mathrm{MHz}$ for ${ }^{1} \mathrm{H}, 62.9 \mathrm{MHz}$ for ${ }^{13} \mathrm{C}$, chemical shifts in ppm from internal tetramethylsilane. ${ }^{b}$ Parts per billion/deg, temperature range $22-52{ }^{\circ} \mathrm{C}$. ${ }^{c} \delta\left(\mathrm{Me}_{2} \mathrm{SO}-d_{6}\right)-\delta\left(\mathrm{CDCl}_{3}\right)$; carried out at $5 \mathrm{mg} / 0.5 \mathrm{~mL}$ concentration (Figures 5 and 6). ${ }^{d}$ Under the aromatics, estimated maximum chemical shift. e Upfield resonance positions are estimated from two-dimensional NMR spectra. $J$-coupled systems were observed via COSY spectra and conformational isomers via two-dimensional NOE spectra. Prolines could not be uniquely assigned. ${ }^{f}$ Proline assignments are not definitive; those presented are based on arguments from previous cyclic pentapeptides.
trans-Pro ring carbon resonance positions. The other proline in the cyclic pentapeptide has ${ }^{13} \mathrm{C}$ resonance positions with typical values for prolines not participating in $\gamma$-turn conformations and experiencing no unusual steric effects.

Titration of a $\mathrm{CDCl}_{3}$ solution of cyclo(Ala-Pro-Gly-D-Phe-Pro) with $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$ causes decreased intensity and pronounced shifts of resonances of the all-trans conformer, increased intensity and shifting of resonances from the one-cis form, and some alterations of coupling constants for both species (Figures 5 and 6). It is evident that modest conformational rearrangement within the all-trans form occurs concurrent with the shift in the all-trans/ one-cis equilibrium. The Gly NH of the all-trans form undergoes the largest shift in resonance position upon addition of small amounts of $\mathrm{Me}_{2} \mathrm{SO}-d_{6}$, followed by the NH of the D -Phe, then that of the Ala (Figure 6). At $100 \% \mathrm{Me}_{2} \mathrm{SO}-d_{6}$, such a small amount of the all-trans form is present that analysis of its spectral parameters is not possible. Interestingly, another slowly interconverting conformer appears in small concentration in the high [ $\mathrm{Me}_{2} \mathrm{SO}$ ] ranges of the titration. This minor conformer must arise from a two-cis or the alternate one-cis isomer of the pentapeptide ring.
Model building together with fitting of observed NMR parameters leads to the suggestion that the following all-trans conformation is a major contributor to the conformational distribution of cyclo(Ala-Pro-Gly-D-Phe-Pro) in $\mathrm{CDCl}_{3}$ :

|  | Ala | Pro | Gly | D-Phe | Pro |
| ---: | ---: | ---: | ---: | ---: | ---: |
| $\phi$ | -160 | -60 | 90 | 150 | -75 |
| $\psi$ | -170 | 90 | 40 | -130 | 50 |

Note that this conformation (illustrated in Figure 8) is a somewhat modified version of the preferred all-trans conformation of $c y$ -clo(Gly-Pro-Gly-D-Ala-Pro) ${ }^{2}$ and cyclo(D-Phe-Pro-Gly-D-AlaPro) ${ }^{12}$ (Figure 2). There is a weak $\gamma$ turn within the Pro-Gly type II $\beta$ turn, and the D-Phe-Pro-Gly sequence does not take up a $\gamma$

Figure 8. Diagram of cyclo(Ala-Pro-Gly-D-Phe-Pro) in the all-trans conformation proposed to exist in $\mathrm{CDCl}_{3}$ solution on the basis of model building from NMR data. This conformation probably represents an average structure; other $\phi, \psi$ values for $\mathrm{Gly}^{3}$ seem particularly accessible. In building this structure, cyclization was achieved most readily with the Pro-Ala bond adopting an $\omega$ value of $-160^{\circ}$, as has been seen in other of the cyclic pentapeptides. ${ }^{3.5}$
turn. The altered backbone geometry appears to accommodate the Ala $\mathrm{CH}_{3}$ with reduced crowding.

The introduction of an L residue preceding a proline in cyclo-(Ala-Pro-Gly-D-Phe-Pro) has markedly changed the conformational preferences of the pentapeptide backbone compared to a nalogous peptides with a D residue or Gly preceding Pro. Empirical energy calculations have shown that the $\mathrm{L}-\mathrm{X}$-L-Pro sequence places significant constraints on the conformational space available to a peptide. ${ }^{17}$ Previous work with the cyclo(L-X-Pro-D-Y[Gly]) ${ }_{2}$ hexapeptides found a similar conformational interconversion to that seen here, which also was strongly correlated with the size of the side chain of L-X and with the polarity of the solvent. ${ }^{16,18,19}$ As observed for the cyclic pentapeptide in the present study, $\mathrm{Me}_{2} \mathrm{SO}$ favors the cis form of the cyclic hexapeptides and $\mathrm{CDCl}_{3}$ the trans. Interestingly, in neither the cyclic hexa-nor pentapeptide cis conformers are there any intramolecular hydrogen bonds. ${ }^{19}$ Fundamental characteristics of this local dipeptide sequence appear to influence strongly the relative energies of peptide conformational states; the preferred conformation is not only a function of constraints specific to the cyclic hexa- or pentapeptide ring.

Acknowledgment. This research has been supported in part by NIH Grants GM30902 (to I.L.K) and GM27616 (to L.M.G.). L.M.G. is a Fellow of the A. P. Sloan Foundation (1984-1986).

Registry No. cyclo(Ala-Pro-Gly-D-Phe-Pro), 81163-79-3.
Supplementary Material Available: Table of anisotropic thermal parameters, fractional coordinates of hydrogen atoms, and observed and calculated structure factors ( 10 pages). Ordering information is given on any current masthead page.
