# Reductive Coupling of Pyridazine and Benzaldehyde Azine and Reduction of Bipyridine by $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}{ }^{1}$ 

William J. Evans* and Donald K. Drummond<br>Contribution from the Department of Chemistry, University of California, Irvine, Irvine, California 92717. Received August 20, 1988

#### Abstract

C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}\) reacts with pyridazine in toluene to form in high yield the complex $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}(\mathrm{THF}) \mathrm{Sm}\right]_{2}-$ $\left[\mu, \eta^{4} \cdot\left(\widehat{\mathrm{CH}=\mathrm{NNCH}=\mathrm{CHC}} \mathrm{N}_{-}\right)_{2}(1)\right.$, which contains a bipyridazine moiety formed by coupling two pyridazine molecules at the 4 -position. The complex crystallizes from toluene with three toluene molecules of crystallization in space group $P \overline{1}$ with $a=10.449$ (3) $\AA, b=11.018$ (2) $\AA, c=16.549$ (4) $\AA, \alpha=102.03(2)^{\circ}, \beta=98.51(2)^{\circ}, \gamma=97.95(2)^{\circ}$, and $D_{\text {calce }}$ $=1.14 \mathrm{~g} \mathrm{~cm}^{-3}$ for $Z=1$. Least-squares refinement on the basis of 4276 unique observed reflections converged to a final $R$ $=0.043$. Each trivalent bent metallocene unit, ( $\left.\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$, is coordinated by a THF molecule $[\mathrm{Sm}-\mathrm{O}=2.555$ (5) $\AA$ ] and the adjacent nitrogen atoms of an $\mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}$ ring $[\mathrm{Sm}-\mathrm{N}=2.351$ (6) and 2.430 (6) $\AA ; \mathrm{N}-\mathrm{N}=1.379$ (9) $\AA$ ]. Benzaldehyde azine, $\mathrm{PhHC}=\mathrm{NN}=\mathrm{CHPh}$, is also reductively coupled via $\mathrm{C}-\mathrm{C}$ bond formation by $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$. The product of this reaction is $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\right]_{2}\left[\mu, \eta^{4}-(\mathrm{PhHC}=\mathrm{NNCHPh})_{2}\right]$ (2). This complex crystallizes from toluene/THF with six THF molecules and a toluene molecule of crystallization per two formula units in space group $P \overline{1}$ with $a=14.674$ (6) $\AA, b=17.806$ (6) $\AA, c=17.757$ (6) $\AA, \alpha=90.72(3)^{\circ}, \beta=114.36(3)^{\circ}, \gamma=108.24$ (3) ${ }^{\circ}$, and $D_{\text {calcd }}=1.28 \mathrm{~g} \mathrm{~cm}^{-3}$ for $Z=2$. Least-squares refinement on the basis of 6929 unique observed reflections converged to a final $R=0.082$. Each trivalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ unit is coordinated by two nitrogen atoms with $\mathrm{Sm}-\mathrm{N}$ distances of 2.315 (13) and 2.431 (14) $\AA$ for one Sm and 2.350 (12) and 2.411 (13) $\AA$ for the other. The $\mathrm{N}-\mathrm{N}$ distances are 1.34 (2) and 1.35 (2) $\AA$. $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ reduces bipyridine to form the $\mathrm{Sm}^{3+}$ bipyridyl complex $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\left(\eta^{2}-\mathrm{N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)(3)$ which crystallizes from toluene in space group $P \overline{1}$ with a $=9.4667$ (12) $\AA, b=9.6784$ (16) $\AA, c=15.5870$ (19) $\AA, \alpha=81.506$ (12) $, \beta=81.033(10), \gamma=71.803$ (12), and $D_{\text {calcd }}=1.44 \mathrm{~g}$ $\mathrm{cm}^{-3}$ for $Z=2$. Least-squares refinement on the basis of 5422 unique observed reflections converged to a final $R=0.026$. The bent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ unit is coordinated by the bipyridyl nitrogen atoms via 2.427 (2) and 2.436 (2) $\AA$ distances.

A recent development in the use of metal-containing reagents in organic chemistry involves the $\mathrm{Sm}(\mathrm{II})$ ion ${ }^{2,3}$ and $\mathrm{SmI}_{2}(\mathrm{THF})_{2}{ }^{4,5}$ is being studied with increasing frequency in this regard. ${ }^{6}$ The organometallic complex ( $\left.\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}{ }^{7}$ is also being used to probe the range of reactivity accessible via $\operatorname{Sm}(\mathrm{II}){ }^{8,9}$ The latter complex can display chemistry different from $\mathrm{SmI}_{2}(\mathrm{THF})_{2}$ and often provides crystallographically characterizable metal-containing reaction products.
Studies of the reactivity of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ with $\mathrm{CO},{ }^{10}$ $\mathrm{RC} \equiv \mathrm{CR},{ }^{11} \mathrm{RN}=\mathrm{NR},{ }^{12,13}$ and $\mathrm{R}_{2} \mathrm{C}=\mathrm{CR}_{2}{ }^{14}$ have revealed that

[^0]Sm(II) can effect a variety of unusual and potentially useful transformations with these unsaturated substrates. These include the reductive homologation of three molecules of CO to the ketene carboxylate $\mathrm{O}_{2} \mathrm{CC}=\mathrm{C}=\mathrm{O}^{2-},{ }^{10}$ the formation of a stereospecifically substituted indenoindenediolate complex from diphenylethyne and $\mathrm{CO},{ }^{11}$ and the double insertion of CO into the $\mathrm{N}=\mathrm{N}$ bond of azobenzene ${ }^{13}$ and the $\mathrm{C}=\mathrm{C}$ bond of bis(2-pyridyl)ethene. ${ }^{14}$

The reactions cited above, which had no precedents in organometallic chemistry, demonstrated that ( $\left.\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ could reduce unsaturated substrates in surprising ways. Accordingly, we felt it was appropriate to explore a wide variety of unsaturated substrates to fully define the possible reactivity patterns available to $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$. In this report, we describe reactions with some substrates containing $\mathrm{N}-\mathrm{C}$ double bonds. Given the strong reducing power of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ and the reduction potentials of the substrates, reactivity was expected. However, in contrast to the two electron multiple bond reduction observed for the $\mathrm{RC} \equiv \mathrm{CR}, \mathrm{RN}=\mathrm{NR}$, and $\mathrm{R}_{2} \mathrm{C}=\mathrm{CR}_{2}$ substrates, we find that azines are reduced by one electron per substrate to cleanly form coupled moieties not readily available via electrochemical reduction.

## Experimental Section

The complexes described in this paper are air- and moisture-sensitive. Therefore, all syntheses and subsequent manipulations were conducted under nitrogen using Schlenk, vacuum-line, and glove-box (Vacuum Atmospheres HE-553 Dri-Lab) techniques. $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ and the solvents were prepared as previously described. ${ }^{5}$ Pyridazine, benzaldehyde azine, and bipyridine were obtained from Aldrich and degassed at room temperature before use. NMR spectra, ${ }^{7}$ IR spectra, ${ }^{7}$ magnetic susceptibility measurements, ${ }^{7}$ and complexometric analyses ${ }^{15}$ were obtained as previously described. UV-visible spectra were recorded on a Perkin-Elmer Lambda 4A spectrometer.
$\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}(\mathrm{THF}) \mathrm{Sm}\right]_{2}\left[\mu, \eta^{4}-(\mathrm{CH}=\mathrm{NNCH}=\mathrm{CHCH}-)_{2}\right]$ (1). In the glove box, pyridazine, $\mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}$ ( $36 \mathrm{mg}, 0.44 \mathrm{mmol}$ ), in 5 mL of toluene was added to a purple solution of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}(254 \mathrm{mg}, 0.44$ mmol ) in 10 mL of toluene. The solution turned yellow-orange immediately. The solution was stirred for 1 h ; the solvent was removed by rotary evaporation, and crude 1 was isolated as an orange powder (250

mg, $98 \%$ ), which was $>95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR spectroscopy. Orange crystals of 1 were obtained from a concentrated toluene solution cooled to $-34^{\circ} \mathrm{C}(144 \mathrm{mg}, 57 \%)$. Anal. Calcd for $\mathrm{SmC}_{28} \mathrm{H}_{42} \mathrm{~N}_{2} \mathrm{O}: \mathrm{Sm}, 26.2$. Found: $\mathrm{Sm}, 25.6 .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 8.53$ (br s, $1 \mathrm{H}, \mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}$ ), 5.64 (br s, $\left.1 \mathrm{H}, \mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}\right), 4.24\left(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, \mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}\right), 4.19\left(\mathrm{br} \mathrm{s}, 1 \mathrm{H}, \mathrm{N}_{2} \mathrm{C}_{4} \mathrm{H}_{4}\right)$, $1.29\left(\mathrm{~s}, 30 \mathrm{H}, \mathrm{C}_{5} \mathrm{Me}_{5}\right),-0.253\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right),-0.514\left(\mathrm{~s}, 4 \mathrm{H}, \mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}\right)$, the signals labeled br have line widths of $6-10 \mathrm{~Hz}$ at half-height. ${ }^{13} \mathrm{C}$ NMR ( $\mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 111.8\left(\mathrm{~s}, \mathrm{C}_{5} \mathrm{Me}_{5}\right), 67.0\left(\mathrm{t}, J_{\mathrm{CH}}=144 \mathrm{~Hz}, \mathrm{THF}\right), 23.8$ $\left(\mathrm{t}, J_{\mathrm{CH}}=132 \mathrm{~Hz}\right.$, THF), $17.5\left(\mathrm{q}, J_{\mathrm{CH}}=125 \mathrm{~Hz}, \mathrm{C}_{5} \mathrm{Me} 5\right)$. The ${ }^{13} \mathrm{C}$ NMR $\mathrm{C}_{5} \mathrm{Me}_{5}$ shifts are characteristic of Sm (III) complexes. ${ }^{16,17}$ IR (KBr): 2980-2860 (s), 1600 (m), 1555 (w), 1535 (w), 1495 (w), 1445 (s), 1380 (m), 1315 (w), 1300 (w), 1220 (s), 1115 (m), 1025 (s), $910(\mathrm{~s})$, 875 (s), 810 (w), 730 (s), 710 (s), 695 (s), $655(\mathrm{~m}) \mathrm{cm}^{-1}$.

X-ray Crystallography of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \text { (THF)Sm }\right]_{2}\left[\mu, \eta^{4}\right.$-( $\mathbf{C H}=\mathrm{NNCH}=$ $\left.\mathbf{C H C H}-)_{2}\right] \cdot 3 \mathrm{C}_{7} \mathrm{H}_{8}$. General procedures for data collection and reduction have been described previously. ${ }^{18}$ An orange crystal measuring 0.10 mm $\times 0.30 \mathrm{~mm} \times 0.40 \mathrm{~mm}$ was sealed under nitrogen in a glass capillary and mounted on a Nicolet $\mathrm{R} 3 \mathrm{~m} / \mathrm{V}$ diffractometer. Lattice parameters were determined at $24^{\circ} \mathrm{C}$ from the angular settings of 20 computer-centered reflections. Data were collected by the $\theta-2 \theta$ scan technique in bisecting geometry. The $p$ factor in the expression ${ }^{19}$ for the standard deviation of the observed intensities was given a value of 0.05 . Relevant crystal and data collection parameters are given in Table I. During the data collection, the intensities of three standard reflections measured every 100 reflections showed a linear decay of $7 \%$; the intensities were corrected for this decay. An absorption correction was applied. Patterson and difference Fourier techniques were used to locate all non-hydrogen atoms. All atoms except the carbon atoms in one of the toluene molecules were

data collection the intensities of three standard reflections measured every 100 reflections showed only random fluctuations within $\pm 3 \%$. An empirical absorption correction was applied. Patterson and difference Fourier techniques were used to locate all non-hydrogen atoms. All atoms except those in the solvent molecules were refined with anisotropic temperature parameters by use of full-matrix least-squares methods. The solvent molecules, which were refined isotropically, were disordered and severely limited the quality of the structure. No hydrogen atoms were located. A final difference map contained no recognizable features; its largest peak was of height $4.2 \mathrm{e} / \AA^{3}$ at a distance of $1.27 \AA$ from $\operatorname{Sm}(2)$ and this reflected the poor quality of the structure. Final fractional coordinates are given in Table III.
$\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\left(\eta^{2}-\mathrm{N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)$ (3). In the glove box $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ $(350 \mathrm{mg}, 0.619 \mathrm{mmol})$ and bipyridine ( $97 \mathrm{mg}, 0.621 \mathrm{mmol}$ ) were dissolved together in toluene. The solution turned orange-brown immediately and was stirred overnight. The solvent was removed by rotary evaporation leaving 3 as a brown powder ( $346 \mathrm{mg}, 97 \%$ ). Dark brown crystals of 3 were grown from toluene at $-34^{\circ} \mathrm{C}$. Anal. Caled for $\mathrm{SmC}_{30} \mathrm{H}_{38} \mathrm{~N}_{2}$ : Sm, 26.1. Found: $\mathrm{Sm}, 26.1 .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right): \delta 2.49$ (s, $\mathrm{C}_{5} \mathrm{Me}_{5}$ ), -13.4 (br, $\Delta \nu_{1 / 2}=100 \mathrm{~Hz}$ ), $-26.0\left(\mathrm{br}, \Delta \nu_{1 / 2}=250 \mathrm{~Hz}\right) .{ }^{13} \mathrm{C}$ NMR ( $\mathrm{C}_{6} \mathrm{D}_{6}$ ): $\delta 136.3\left(\mathrm{~s}, \mathrm{C}_{5} \mathrm{Me}_{5}\right), 9.0\left(\mathrm{q}, J_{\mathrm{CH}}=125 \mathrm{~Hz}, \mathrm{C}_{5} M e_{5}\right)$. IR (KBr): 2950 (s), 1540 (m), 1500 (sh, m), 1490 (s), 1480 (s), 1440 (s), 1420 (s), $1380(\mathrm{~m}), 1320(\mathrm{w}), 1290(\mathrm{~m}), 1280(\mathrm{~m}), 1265(\mathrm{~s}), 1210(\mathrm{~m})$, $1150(\mathrm{~s}), 1080(\mathrm{~m}), 1025(\mathrm{sh}, \mathrm{m}), 1015(\mathrm{~s}), 1005(\mathrm{~s}), 940(\mathrm{~s}), 760(\mathrm{w})$, $745(\mathrm{w}), 715(\mathrm{~m}) \mathrm{cm}^{-1} \cdot \chi_{\mathrm{M}}{ }^{298 \mathrm{~K}}=2400 \times 10^{-6}(\mathrm{cgs}), \mu_{\mathrm{eff}}{ }^{298 \mathrm{~K}}=2.4 \mu_{\mathrm{B}}$. UV-vis $\left(2.4 \times 10^{-4} \mathrm{M}\right.$ in toluene, $\left.\lambda_{\max } \mathrm{nm},(\epsilon)\right): 524(1700), 491(1200)$, 393 (4000), 285 (6700).

X-ray Crystallography of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\left(\eta^{2}-\mathrm{N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)$ (3). A dark brown crystal measuring $0.50 \mathrm{~mm} \times 0.50 \mathrm{~mm} \times 0.70 \mathrm{~mm}$ was handled and analyzed as described above for 1 (including the same weighting scheme). Relevant crystal and data collection parameters are given in Table I. During the data collection, the intensities of three standard

Figure 1. Molecular structure of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}(\mathrm{THF}) \mathrm{Sm}\right]_{2}\left[\mu, \eta^{4}-\right.$ $(\widehat{\mathrm{CH}=\mathrm{NNCH}=\mathrm{CHCH}}-)_{2}$ ] (1).
reflections measured every 100 reflections showed only random variation within $\pm 1 \%$. An empirical absorption correction was applied. Patterson and difference Fourier techniques were used to locate all non-hydrogen atoms which were refined with anisotropic temperature parameters by use of full-matrix least-squares methods. All hydrogen atoms were observed on a difference map. The methyl hydrogens on the pentamethylcyclopentadienyl rings were included in their idealized ( $\mathrm{C}-\mathrm{H}=$ $0.95 \AA$ ) positions. The hydrogen atoms of the bipyridyl rings were refined isotropically. A final difference map contained no recognizable features; its largest peak was of height $1.7 \mathrm{e} \AA^{-3}$ at a distance of $0.84 \AA$ from Sm. Fractional coordinates are given in Table IV.

## Results

The reactions of the purple complex $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ with the nitrogen-containing substrates pyridazine, benzaldehyde azine, and bipyridine are all characterized by rapid color changes to orange or orange-brown. This is consistent with a rapid oxidation of Sm(II) to Sm(III). ${ }^{9}$ In each case, the newly formed organosamarium complex was characterized by complexometric analysis, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy, and IR spectroscopy and was identified by X-ray crystallography.

Pyridazine. The structure of complex 1, obtained from the reaction of pyridazine with $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$, is shown in Figure 1. The X-ray analysis revealed that reductive carboncarbon bond formation occurred in this reaction according to eq 1. A bipyridazine unit $h_{i}$ been formed in which the two nitrogen

atoms of each ring coordinate to a $\mathrm{Sm}(\mathrm{THF})\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}$ moiety. The molecule contains an inversion center which lies at the midpoint of the $\mathrm{C}(23)-\mathrm{C}\left(23^{\prime}\right)$ bond, which is the new $\mathrm{C}-\mathrm{C}$ bond formed in the reaction. Bond distances and angles are given in Table V and in the supplementary material.
The C(23)-C(23') distance of 1.545 (17) $\AA$ is typical of a C-C single bond and the bond angles around $C(23)$ are consistent with an $\mathrm{sp}^{3}$ center. As shown in Table V , the $\mathrm{C}(23)-\mathrm{C}(22)$ and C -(23)-C(24) bond distances are clearly in the single-bond range and the $C(22)-C(21)$ distance is in the double-bond range. ${ }^{22}$ Hence, the delocalized bonding found in pyridazine, which has $\mathrm{C}-\mathrm{C}$ lengths of 1.375 (1) and 1.393 (2) $\AA,{ }^{23}$ is not present in 1. The $\mathrm{C}(24)-\mathrm{N}(2)$ bond of 1.29 (1) $\AA$ is shorter and the $\mathrm{C}(21)-$ $\mathrm{N}(1)$ bond of 1.40 (1) $\AA$ is longer than the analogous 1.341 (2) $\AA \mathrm{C}-\mathrm{N}$ bond in pyridazine. These distances in 1 are consistent with a double and a single bond, respectively. ${ }^{24}$ The $\mathrm{N}(1)-\mathrm{N}(2)$

distance of 1.379 (9) $\AA$ is larger than the 1.330 (1) $\AA$ length in pyridazine and suggests that the double-bond character present in pyridazine has been lost after the reductive coupling and complexation by samarium.

These distances and normal valence considerations suggest the following formal bonding arrangements between the nitrogen atoms and the samarium atoms. $\mathrm{N}(1)$ can bind to samarium via a single bond of the $\mathrm{Sm}-\mathrm{NR}_{2}$ type. $\mathrm{N}(2)$ coordinates to samarium via its lone pair in a $\mathrm{Sm} \leftarrow: \mathrm{NR}_{3}$ type donor bond. Consistent with this the $\mathrm{Sm}-\mathrm{N}(1)$ bond of 2.351 (6) $\AA$ is very close to the $\mathrm{Sm}-\mathrm{NR}_{2}$ single-bond distance of 2.333 (9) $\AA$ in $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)(\mathrm{THF}) \mathrm{Sm}\right]_{2}-$ [ $\left.\mu, \eta^{2}, \eta^{2}-\mathrm{PhNNPh}\right]_{2}{ }^{25}$ and agrees with the $\mathrm{Y}-\mathrm{NR}_{2}$ single-bond distances of 2.253 (5) and 2.274 (5) $\AA$ in $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{YN}\left(\mathrm{SiMe}_{3}\right)_{2}{ }^{26}$ after adding $0.06^{27}-0.084 \AA^{28}$ to account for the radial difference in the metals. The $\mathrm{Sm}-\mathrm{N}(2)$ length of 2.430 (6) $\AA$ is longer than

[^3]

Figure 2. Molecular structure of $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\right]_{2}\left[\mu, \eta^{4}-(\mathrm{PhCH}=\right.$ NNCHPh- $)_{2}$ (2).
a typical $\mathrm{Sm}-\mathrm{NR}_{2}$ single bond, but it is shorter than the range expected for $\mathrm{Sm} \leftarrow: \mathrm{NR}_{3}$ donor bonds: $2.5-2.8 \AA . .^{25,29}$ A specific example of this in a complex which is similarly ligated is the 2.539

Benzaldehyde Azine. The structure of complex 2 (Figure 2) revealed another example of reductive coupling effected by $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ as shown in eq $2\left(\mathrm{Cp}^{5}=\mathrm{C}_{5} \mathrm{Me}_{5}, \mathrm{Ph}=\mathrm{C}_{6} \mathrm{H}_{5}\right)$.

As in the synthesis of 1 , a bimetallic complex is obtained in which each $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ unit is coordinated to two adjacent nitrogen atoms. In contrast to $\mathbf{1 , 2}$ crystallizes without a THF coordinated to the samarium atom; hence, the metal is eight coordinate.
Since crystals of $\mathbf{2}$ readily desolvated and the solvent in the lattice was disordered, the quality of the structural data on $\mathbf{2}$ is not optimum. However, the connectivity of the atoms is welldefined and the bond distances and angles (Table VI) are similar to those for complex 1. The average $\mathrm{Sm}-\mathrm{C}$ (ring) distance of 2.76 (2) $\AA$, the average (ring centroid)-Sm-(ring centroid) angle of $133^{\circ}$, the $\mathrm{Sm}-\mathrm{N}$ distances, and the $\mathrm{N}-\mathrm{N}$ distances are equivalent to those in 1. The N - C distances are either in the single- or double-bond range, ${ }^{24}$ not in between, and eq 2 shows their arrangement in 2 . The $C(41)-C(55)$ bond of 1.60 (2) $\AA$ which links the two benzaldehyde azines is in the single-bond range. ${ }^{22}$

Bipyridine. The reaction of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ with bipyridine differs from the reactions discussed above. With bipyridine a monometallic complex, $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\left(\eta^{2}-\mathrm{N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)$ (3), is isolated. The room temperature magnetic susceptibility of this complex, $\chi_{M}=2400 \times 10^{-6}(\mathrm{cgs})$, is in between the $(700-1500) \times 10^{-6}(\mathrm{cgs})$ range observed for trivalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ systems and the (4800-6000) $\times 10^{-6}(\mathrm{cgs})$ range observed for divalent complexes containing the $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ unit. ${ }^{21}$ The ${ }^{13} \mathrm{C}$ NMR shifts for the $\mathrm{C}_{5} \mathrm{Me}_{5}$ carbon atoms are characteristic of $\mathrm{Sm}(\mathrm{III})$ complexes rather than Sm (II) systems. ${ }^{16,17}$ Specifically, we have observed that for trivalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ complexes, the ring carbons resonate in the range $113-121 \mathrm{ppm}$ and the methyl carbons in the range $18-28 \mathrm{ppm} .{ }^{13,14,16}$ For divalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ complexes, the ring

Figure 3. Molecular structure of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\left(\eta^{2}-\mathrm{N}_{2} \mathrm{C}_{8} \mathrm{H}_{10}\right)$ (3).
carbons are found from -73 to -99 ppm and the methyl carbons are at $94-100 \mathrm{ppm}$. ${ }^{7.17}$

Consistent with this apparent oxidation of samarium, the infrared spectrum of 3 exhibits absorptions more typical of a bipyridyl anion ${ }^{32}$ than of a neutral bipyridine ligand. ${ }^{32,33}$ In particular, the infrared spectrum of $\mathbf{3}$ has a strong band in the $900-1000-\mathrm{cm}^{-1}$ region and several strong to medium intensity bands in the $1490-1575-\mathrm{cm}^{-1}$ range. These are two characteristic features of reduced bipyridyl systems which differ from neutral bipyridine complexes. ${ }^{32}$ In addition, the strong absorption in the $755-\mathrm{cm}^{-1}$ region attributed to an out of plane CH bending mode ${ }^{34}$ in bipyridine and neutral bipyridine complexes ${ }^{33}$ is absent from the spectrum of 3 . The infrared spectrum of $\mathrm{Li}(\text { bipy })^{32}$ similarly lacks this absorption.

The UV-visible spectrum of $\mathbf{3}$ shows four main peaks (with several shoulders) in three different wavelength regions. The spectrum is not similar to that of free bipyridine ${ }^{35}$ or bipyridyl dianion. ${ }^{36,37}$ The presence of three regions of absorption in the spectrum of 3 is similar to spectra of bipyridyl monoanion ${ }^{36,37}$ and complexes of bipyridyl monoanion. ${ }^{37-39}$

The structure of $\mathbf{3}$ is shown in Figure 3, and bond distances and angles are given in Table VII. The overall geometry of 3 is typical of both divalent and trivalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{X})(\mathrm{Y})$ complexes. The plane defined by Sm and the two nitrogen atoms forms a $90.5^{\circ}$ dihedral angle with the plane defined by Sm and the two $\mathrm{C}_{5} \mathrm{Me}_{5}$ ring centroids. The $\mathrm{Sm}-\mathrm{C}$ (ring) average distance of 2.724 (3) $\AA$ is consistent with a trivalent-metal center. The range of $\mathrm{Sm}-\mathrm{C}$ (ring) averages for trivalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ complexes is $2.68-2.77 \AA$ compared to 2.79 (1)-2.86 (1) $\AA$ for divalent $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}$ species. ${ }^{16,17}$ The $\mathrm{Sm}-\mathrm{N}$ distances of 2.427 (2) and 2.436 (2) $\AA$ are somewhat longer than the $2.31-2.36 \AA$ typical for simple $\mathrm{Sm}(\mathrm{III})-\mathrm{NR}^{2}$ bonds (see above) and shorter than the $2.5 \rightarrow 2.8 \AA$ range typical for $\mathrm{Sm}(\mathrm{III}) \leftarrow \mathrm{NR}_{3}$ bonds. This is consistent with a one-electron reduction of bipyridine in 3 .

Comparisons of these $\mathrm{Sm}-\mathrm{N}$ distances with the $\mathrm{Nd}-\mathrm{N}$ distances in the lanthanide bipyridine complex $\mathrm{Nd}(\mathrm{TTA})_{3}\left(\mathrm{~N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)^{40}(\mathbf{4})$ (TTA $=$ thenoyltrifluoroacetonato) also support this idea. Eight-coordinate 4 has an average Nd-N distance of 2.71 (2) $\AA$. Since eight-coordinate $\mathrm{Nd}($ III $)$ is larger than eight-coordinate Sm(III) by $0.03 \AA \AA^{27}$ a $\operatorname{Sm}$ (III)-N(neutral bipyridine) bond of $2.68 \AA$ would be expected. The bond length in $\mathbf{3}$ is considerably shorter. $\mathrm{Ln}-\mathrm{N}$ bond length comparisons with $\mathrm{La}\left(\eta^{2}-\mathrm{NO}_{3}\right)_{3^{-}}$ $\left(\mathrm{N}_{2} \mathrm{C}_{10} \mathrm{H}_{8}\right)_{2}{ }^{41}(5)$ are less direct since the bipyridine ligand in 5

has $\mathrm{C}-\mathrm{C}$ distances different from free bipyridine (see below). The La-N distance in 5 is 2.66 (1) $\AA$ and the metal is ten coordinate. Since ten-coordinate $\mathrm{La}($ III ) is larger than eight-coordinate Sm(III) by $0.19 \AA,{ }^{27}$ this would predict a Sm (III) -N (neutral bipyridine) bond of $2.47 \AA$, if the bipyridine ligand in 5 is neutral. This $\mathrm{Ln}-\mathrm{N}$ length is much closer to that in 3.
The $\mathrm{Sm}-\mathrm{N}$ distances in $\mathbf{3}$ are shorter than those expected for a $\mathrm{Sm}(\mathrm{II})-\mathrm{NR}_{2}$ or $\mathrm{Sm}(\mathrm{II}) \longleftarrow: \mathrm{NR}_{3}$ interaction. The bond lengths in $\mathbf{3}$ are less than the $\mathrm{Sm}(\mathrm{II})-\mathrm{NR}_{2}$ single bond distances found in formally four-coordinate $\left[\left(\mathrm{Me}_{3} \mathrm{Si}\right)_{2} \mathrm{~N}\right]_{2} \mathrm{Sm}(\mathrm{THF})_{2}, 2.43$ (1) $\AA$, and formally six-coordinate $\left\{\left[\left(\mathrm{Me}_{3} \mathrm{Si}\right)_{2} \mathrm{~N}\right] \mathrm{Sm}(\mathrm{THF})(\mathrm{DME})(\mu-\mathrm{I})\right\}_{2}$, 2.455 (7) $\AA, 42$ after taking into account the difference in coordination number. ${ }^{27}$ The $\mathrm{Sm}-\mathrm{N}$ distances in $\mathbf{3}$ are also shorter than the $\mathrm{Sm}(\mathrm{II}) \leftarrow: \mathrm{NR}_{3}$ donor bond distance of 2.596 (8) $\AA$ found in six-coordinate $\left[\mathrm{SmI}_{2}\left(\mathrm{NCCMe}_{3}\right)_{2}\right]_{n}{ }^{43}$

The metrical parameters in the bipyridyl ligand also suggest the presence of a reduced bipyridyl ligand. The greatest difference among the bipyridyl ligand in 3 , free bipyridine, ${ }^{4,45}$ and bipyridine in 4 and 5 is the $\mathrm{C}-\mathrm{C}$ length connecting the pyridine rings. In 3 it is 1.429 (4) $\AA$ compared to 1.490 (3) $\AA$ in the free ligand, 1.50 (3) $\AA$ in 4 and 1.450 (17) $\AA$ in 5 . The $\mathrm{C}-\mathrm{N}$ and $\mathrm{C}-\mathrm{C}$ average lengths in $3,1.37$ (1) and 1.38 (3) $\AA$, respectively, do not differ greatly from those in free bipyridine $[1.344$ (2) and 1.387 (2) $\AA$ ], 4 [1.38 (3) and 1.42 (4) $\AA$ ], and 5 [1.34 (1) and 1.41 (1) $\AA$ ]. However, the arrangement of the long and short $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{N}$ bonds in $\mathbf{3}$ is regular and different from that in bipyridine, $\mathbf{4}$, and 5. The bonding in the bipyridyl ligand in 3 apparently has increased contributions from resonance structures containing double bonds between $\mathrm{C}(21)$ and $\mathrm{C}(26), \mathrm{N}(1)$ and $\mathrm{C}(25), \mathrm{C}(25)$ and $C(24)$, and $C(22)$ and $C(23)$ (and the corresponding atoms on the other ring). This pattern is very similar to that observed in $\mathrm{Mo}(\mathrm{OPr}-i)_{2}\left(\mathrm{C}_{10} \mathrm{H}_{4} \mathrm{~N}_{2}\right)_{2}{ }^{45}$ and $\left(\eta^{6}\right.$-toluene $) \mathrm{Fe}\left(\mathrm{C}_{10} \mathrm{H}_{8} \mathrm{~N}_{2}\right),{ }^{46}$ both of which contain reduced bipyridyl ligands. All of the above structural data agree with the magnetic data in suggesting that Sm (II) has transferred almost a full electron to bipyridine to form

[^7]a complex which is most closely described as a $\mathrm{Sm}^{3+}$ bipyridyl ${ }^{-}$ compound.

## Discussion

As a result of the large reduction potential of $\mathrm{Sm}(\mathrm{II}),{ }^{47}$ $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ reacts rapidly with pyridazine, benzaldehyde azine, and bipyridine by transferring an electron to the substrate and forming a $\mathrm{Sm}^{3+}$ species. Given the reduction potentials of these substrates (pyridazine, -2.30 V vs SCE in DMF; ${ }^{48}$ benzaldehyde azine, -0.72 V vs SCE ${ }^{49}$ and bipyridine, -1.55 V vs SCE ), ${ }^{50}$ an electron-transfer reaction of this type is expected. In contrast to $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ reduction of other previously studied unsaturated substrates, ${ }^{10,11,13,14}$ these reactions of $\mathrm{C}=\mathrm{N}$ containing molecules do not result in a two-electron reduction of the multiple bond with formation of a $\mathrm{Sm}_{2}$ (substrate) product. Instead, with pyridazine and benzaldehyde azine, $\mathrm{C}-\mathrm{C}$ bond formation occurs, a reaction which is best discussed following a summary of substrate-reduction chemistry.

The reduction of pyridazine has previously been studied in liquid ammonia. A stable radical anion, $\mathrm{C}_{4} \mathrm{~N}_{2} \mathrm{H}_{4}^{-}$, is observed which can be further reduced to a dianion. ${ }^{51}$ Hydrolysis produces dihydropyridazine. The latter product is also obtained when pyridazine is reduced in DMF containing $2-4 \% \mathrm{H}_{2} \mathrm{O} .{ }^{52} \quad 3,6-$ Disubstituted pyridazines are similarly reduced to dihydro species. ${ }^{49,53,54}$ Reduction of benzaldehyde azine in the presence of a proton source gives either $\mathrm{PhCH}=\mathrm{NNH}_{2} \mathrm{CH}_{2} \mathrm{Ph}^{+}$or the cleavage product $\mathrm{PhCH}=\mathrm{NH}_{2}{ }^{+} .49$ Polarographic studies of bipyridine ${ }^{50,54}$ show two reduction waves. The radical anion initially formed can be readily reoxidized to bipyridine. ${ }^{50}$

With $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ as a reductant, pyridazine does not form a dianion $\mathrm{C}_{4} \mathrm{~N}_{2} \mathrm{H}_{4}{ }^{2-}$ which is bound to two $\mathrm{Sm}^{3+}$ ions. Instead, the one electron reduction product couples at the 4 -position to form 1. This is consistent with Hückel calculations which place the most electron density in the radical anion at the 1 - and $4-$ positions. ${ }^{55}$ The probable sequence is shown in eq 3.

The formation of the coupled benzaldehyde azine product 2 could occur in a similar fashion (eq 4). In both cases, the

$\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}^{+}$cation may stabilize the radical anion by coordinating to the two nitrogen positions. The soluble radical intermediate may have a sufficiently long lifetime to give the observed coupled products in high yield. ${ }^{56}$ Such radical coupling is well-established in pyrimidine reductions. ${ }^{56}$ The formation of radicals by the Sm (II) reagent $\mathrm{SmI}_{2}(\mathrm{THF})_{2}$ is also well precedented. ${ }^{2-4}$

In the bipyridine reaction, this coupling does not occur presumably because this substrate can readily delocalize the added electron density. Coordination of the bipyridyl anion to the metal can occur without generating a radical at one specific carbon atom, hence coupling does not occur. Reduced bipyridyl systems of this type have been extensively studied. ${ }^{32,39,45,46,57-60}$

## Conclusion

The reaction of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ with the $\mathrm{C}=\mathrm{N}$-containing substrates discussed in this paper expands the range of substrates which can be reductively activated in special ways by this organosamarium(II) reducing agent. For the azine substrates, a selective high-yield reduction occurs which provides dimeric products not readily accessible using other reducing agents. This example of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ activation of unsaturated substrates differs from previous studies ${ }^{10-14}$ in that the intermediate radicals formed in these reductions dimerize rather than undergo further reduction. The initial one-electron reduction, which is likely to occur in the pyridazine and benzaldehyde azine reactions and which occurs in the bipyridine reaction, is consistent with the reductive chemistry previously observed for $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$. The formation of coupled products rather than doubly reduced species such as $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}\right]_{2} \mathrm{C}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{2}{ }^{9,61}$ and $\left[\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}_{2} \mathrm{~N}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)^{12}\right.$ may be related to the specific nature of the radical intermediate which is formed. Hence, in designed activation of unsaturated substrates by $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$, the stability and location of the initial radical must be considered in order to predict the likely mode of organosamarium activation. Another feature which emerges from this study is the preference for the $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}^{111}$ unit to $\eta^{2}$-coordinate to two adjacent nitrogen atoms. It is too early to assess the importance of this tendency in guiding the course of $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{Sm}(\mathrm{THF})_{2}$ activation reactions, but this type of $\left(\eta^{2}\right.$ $\mathrm{N}, \mathrm{N}) \mathrm{Sm}\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2}$ moiety is becoming increasingly common. ${ }^{25,30}$
