Received June 28, 1993

Organic chemical derivatization of buckminsterfullerene, C<sub>60</sub>, continues to yield fascinating results.<sup>2-4</sup> C<sub>60</sub> is a strong electron acceptor capable of taking on as many as six electrons, and photoexcited  $C_{60}$  is a stronger electron acceptor than  $C_{60}$  in the ground state.<sup>5-7</sup> Although photoinduced charge-transfer between C<sub>60</sub> and various electron donors such as aromatic amines,<sup>5,8</sup> semiconductor colloids,7 porphyrins,9 and photoconducting polymers<sup>10</sup> can occur, there has so far been no example of formation of a photoadduct. Meanwhile, strained Si-Si  $\sigma$  bonds can act as electron donors.<sup>11,12</sup> We report here that the first photochemical reaction of  $C_{60}$  with a disilirane produces a [2 + 3] cycloadduct via a charge-transfer interaction.

Irradiation of a toluene solution of 1,1,2,2-tetramesityl-1,2disilirane<sup>11</sup> (1a,  $3.3 \times 10^{-3}$  M) and C<sub>60</sub> ( $3.3 \times 10^{-3}$  M) with a high-pressure mercury-arc lamp (cutoff < 300 nm) resulted in formation of 1,1,3,3-tetramesityl-1,3-disilolane (2a) in 82% yield<sup>13</sup> with complete consumption of  $C_{60}$  (Scheme I). The adduct 2a

(13) (Mes<sub>4</sub>Si<sub>2</sub>CH<sub>2</sub>)<sub>2</sub>C<sub>60</sub> (FAB MS, *m/z* 1816–1812) was also obtained in 8% yield.

Figure 1. (a) UV-vis spectra of  $C_{60}$  (---) and 2a (---) from 190 to 820 nm in hexane. (b) Time-dependent spectral changes of a toluene solution of C<sub>60</sub> and 1a upon irradiation.

Scheme I

can be readily isolated by preparative HPLC. Very similar results were also obtained with 1,1,2,2-tetrakis(2,6-dimethylphenyl)-1,2-disilirane.<sup>11</sup> The disiliranes were thermally unreactive toward C60 at 90 °C.

FAB mass spectrometry of 2a (C<sub>97</sub>H<sub>46</sub>Si<sub>2</sub>) displays a peak for **2a** at m/z 1270–1266 as well as one for C<sub>60</sub> at 723–720 which arises from the loss of 1a.

The UV-vis absorption spectrum of 2a is virtually identical to that of  $C_{60}$  except for subtle differences in the 400–500 nm region (Figure 1a). Photochemical changes in the absorption spectra are shown in Figure 1b and compared with those of  $C_{60}$ . Interestingly, the spectrum of 2a has absorption features comparable with those of the carbon<sup>3f</sup> and oxygen<sup>4b</sup> analogues of 2a and the related carbene,<sup>3a-d</sup> silvlene,<sup>1</sup> and oxygen<sup>4</sup> adducts, as one would expect from the similarity of the chromophore in these compounds.

The <sup>1</sup>H NMR spectrum of **2a** displays six methyl signals at 3.16, 2.90, 2.41, 2.17, 2.13, and 2.10 ppm and four meta-proton signals of the mesityl groups at 6.68, 6.64, 6.50, and 6.46 ppm.<sup>14</sup> An AB quartet (J = 13.0 Hz) for the two methylene protons at 3.61 and 2.38, ppm supporting  $C_s$  symmetry of the molecule, is also observed. The <sup>13</sup>C NMR spectrum of 2a shows 32 signals for the  $C_{60}$  skeleton.<sup>14</sup> Of the 32, 28 signals have a relative intensity of 2, and four signals have a relative intensity of 1: one at 73.36 ppm and the remainder between 130 and 150 ppm.<sup>15</sup> Twelve signals for four tertiary and eight quaternary aromatic carbon atoms and one signal for the methylene carbon atom of the disilirane component are also observed. These spectral data suggest  $C_s$  symmetry of 2a. Analysis of the C-H three-bond coupling in the H-C COLOC NMR spectrum gave crucial

Figure 2. <sup>1</sup>H NMR spectra of 2a (a) in CS<sub>2</sub>/CD<sub>2</sub>Cl<sub>2</sub> and (b) in CD<sub>3</sub>C<sub>6</sub>D<sub>5</sub> at different temperatures.

evidence for the identification of the 1,3-disilolane structure in 2a. A cross-peak corresponding to a proton of the methylene group and two sp<sup>3</sup> carbon atoms of the fullerene skeleton at 73.36 ppm was observed. The <sup>29</sup>Si NMR spectrum of 2a shows a peak at -9.81 ppm which is assigned to the silicon atom of 2a.<sup>14,16</sup>

Symmetry arguments support the following possibilities: (i) a 5,6-ring junction on the fullerene without free rotation of mesityl groups at 30 °C and with a "frozen" (no ring inversion) single conformer in the envelope conformation; (ii) a 5,6-ring junction on the fullerene without free rotation of mesityl groups at 30 °C; and (iii) a 6,6-ring junction on the C<sub>60</sub> without free rotation of mesityl groups at 30 °C and with a "frozen" conformer (no ring inversion).

To obtain further information on the structure of 2a, the variable-temperature <sup>1</sup>H NMR measurement was carried out<sup>17</sup> (Figure 2). Coalescence of the para-methyl signals at 2.06 and 1.96 ppm at 44 °C reflecting conformational change of the molecule was observed, yielding an activation energy  $\Delta G^{\neq} = 17.0$ kcal/mol.<sup>18</sup> The two pairs of four resonances between 6.7 and 6.3 ppm and between 3.3 and 2.3 ppm also coalesce at 60 °Cand 80 °C, respectively.  $\Delta G^{\neq}$  for both the meta-proton and orthomethyl groups at coalescence temperatures is 16.2 kcal/mol. These results reveal equivalency of methylene, methyl, and aromatic protons over the coalescence temperature and supports hypothesis iii from above.

Hypothesis iii was also supported by AM119 and ab initio 3-21G<sup>20</sup> molecular orbital calculations on the reaction of  $C_{60}$  and disilirane 1b which show that the 6,6-adduct is 16.9 (AM1) and 26.5 (3-21G//AM1) kcal/mol more stable than the 5,6-adduct. The experimental finding for the  $C_s$  structure of 2a (6,6-adduct) was confirmed by the full geometry optimization at the AM1

Figure 3. views of the C, structure of 2a calculated with the AM1 method.

level; its  $C_s$  structure corresponds to an energy minimum and is the most stable. As the optimized structure in Figure 3 shows, four bulky mesityl groups are beautifully spaced in C<sub>s</sub> symmetry with the observed equivalency. The high barrier observed is ascribed to the fact that the space between C<sub>60</sub> and the mesityl groups as well as between mesityl groups becomes filled upon transformation from one envelope-conformer to the other. Such a steric effect was also reflected in the fact that the exothermicity (34.1 kcal/mol) for the addition of 1a to  $C_{60}$  is 43.2 kcal/mol smaller than that (77.3 kcal/mol) of 1b at the AM1 level.

The free energy change ( $\Delta G$ ) from 1a to the triplet state of C<sub>60</sub> is 8.1 kcal/mol.<sup>5a,21</sup> The rate of disappearance of C<sub>60</sub> was suppressed by addition of 10 equiv of diazabicyclo[2.2.2]octane  $(E_p = 0.70 \text{V vs SCE})^{22}$  and 100 equiv of 1,2,4,5-tetramethoxybenzene ( $E_p = 0.79 \text{V} \text{ vs SCE}$ ), each of which has a lower oxidation potential and is unreactive to photoreaction of C<sub>60</sub>. The reaction was completely inhibited by addition of 10 equiv of rubrene as triplet quencher.5a One plausible rationale for these observations is that an exciplex intermediate derived from 1a and the triplet state of C<sub>60</sub> may be responsible for formation of 2a.<sup>23</sup> Further studies on the reaction mechanism are in progress.

Acknowledgment. We thank Professor Takenori Kusumi for helpful discussions on the NMR measurement This work was partly supported by the Ministry of Education, Science, and Culture, Japan, with a Grant-in-Aid for Scientific Research on Priority Area (No. 05233204).
